Installation and Getting Started

Pythons: Python 2.6,2.7,3.3,3.4,3.5, Jython, PyPy-2.3

Platforms: Unix/Posix and Windows

PyPI package name: pytest

dependencies: py, colorama (Windows), argparse (py26).

documentation as PDF: download latest

1.1 Installation

Installation:

```
pip install -U pytest
```

To check your installation has installed the correct version:

```
$ pytest --version
This is pytest version 3.0.2, imported from $PYTHON_PREFIX/lib/python3.5/site-packages/pytest.py
```

1.2 Our first test run

Let's create a first test file with a simple test function:

```
# content of test_sample.py
def func(x):
    return x + 1

def test_answer():
    assert func(3) == 5
```

That's it. You can execute the test function now:

```
$ pytest
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 1 items
```

We got a failure report because our little func (3) call did not return 5.

Note: You can simply use the assert statement for asserting test expectations. pytest's *Advanced assertion introspection* will intelligently report intermediate values of the assert expression freeing you from the need to learn the many names of JUnit legacy methods.

1.3 Running multiple tests

pytest will run all files in the current directory and its subdirectories of the form test_*.py or *_test.py. More generally, it follows *standard test discovery rules*.

1.4 Asserting that a certain exception is raised

If you want to assert that some code raises an exception you can use the raises helper:

```
# content of test_sysexit.py
import pytest
def f():
    raise SystemExit(1)

def test_mytest():
    with pytest.raises(SystemExit):
    f()
```

Running it with, this time in "quiet" reporting mode:

```
$ pytest -q test_sysexit.py
.
1 passed in 0.12 seconds
```

1.5 Grouping multiple tests in a class

Once you start to have more than a few tests it often makes sense to group tests logically, in classes and modules. Let's write a class containing two tests:

```
# content of test_class.py
class TestClass:
    def test_one(self):
        x = "this"
        assert 'h' in x

    def test_two(self):
        x = "hello"
        assert hasattr(x, 'check')
```

The two tests are found because of the standard *Conventions for Python test discovery*. There is no need to subclass anything. We can simply run the module by passing its filename:

The first test passed, the second failed. Again we can easily see the intermediate values used in the assertion, helping us to understand the reason for the failure.

1.6 Going functional: requesting a unique temporary directory

For functional tests one often needs to create some files and pass them to application objects. pytest provides *Builtin fixtures/function arguments* which allow to request arbitrary resources, for example a unique temporary directory:

```
# content of test_tmpdir.py
def test_needsfiles(tmpdir):
    print (tmpdir)
    assert 0
```

We list the name tmpdir in the test function signature and pytest will lookup and call a fixture factory to create the resource before performing the test function call. Let's just run it:

Before the test runs, a unique-per-test-invocation temporary directory was created. More info at *Temporary directories* and files.

You can find out what kind of builtin pytest fixtures: explicit, modular, scalable exist by typing:

```
pytest --fixtures # shows builtin and custom fixtures
```

1.7 Where to go next

Here are a few suggestions where to go next:

- Calling pytest through python -m pytest for command line invocation examples
- good practices for virtualenv, test layout
- pytest fixtures: explicit, modular, scalable for providing a functional baseline to your tests
- Writing plugins managing and writing plugins

Usage and Invocations

2.1 Calling pytest through python -m pytest

New in version 2.0.

You can invoke testing through the Python interpreter from the command line:

```
python -m pytest [...]
```

This is equivalent to invoking the command line script pytest $[\ldots]$ directly.

2.2 Getting help on version, option names, environment variables

```
pytest --version # shows where pytest was imported from
pytest --fixtures # show available builtin function arguments
pytest -h | --help # show help on command line and config file options
```

2.3 Stopping after the first (or N) failures

To stop the testing process after the first (N) failures:

2.4 Specifying tests / selecting tests

Several test run options:

```
# only test_func in test_mod.py
pytest test_mod.py::TestClass::test_method # run a single method in
# a single class
```

Import 'pkg' and use its filesystem location to find and run tests:

```
pytest --pyargs pkg # run all tests found below directory of pkg
```

2.5 Modifying Python traceback printing

Examples for modifying traceback printing:

The --full-trace causes very long traces to be printed on error (longer than --tb=long). It also ensures that a stack trace is printed on **KeyboardInterrrupt** (Ctrl+C). This is very useful if the tests are taking too long and you interrupt them with Ctrl+C to find out where the tests are *hanging*. By default no output will be shown (because KeyboardInterrupt is caught by pytest). By using this option you make sure a trace is shown.

2.6 Dropping to PDB (Python Debugger) on failures

Python comes with a builtin Python debugger called PDB. pytest allows one to drop into the PDB prompt via a command line option:

```
pytest --pdb
```

This will invoke the Python debugger on every failure. Often you might only want to do this for the first failing test to understand a certain failure situation:

```
pytest -x --pdb # drop to PDB on first failure, then end test session
pytest --pdb --maxfail=3 # drop to PDB for first three failures
```

Note that on any failure the exception information is stored on <code>sys.last_value</code>, <code>sys.last_type</code> and <code>sys.last_traceback</code>. In interactive use, this allows one to drop into postmortem debugging with any debug tool. One can also manually access the exception information, for example:

```
>>> import sys
>>> sys.last_traceback.tb_lineno
42
>>> sys.last_value
AssertionError('assert result == "ok"',)
```

2.7 Setting a breakpoint / aka set_trace()

If you want to set a breakpoint and enter the pdb.set_trace() you can use a helper:

```
import pytest
def test_function():
    ...
    pytest.set_trace() # invoke PDB debugger and tracing
```

Prior to pytest version 2.0.0 you could only enter PDB tracing if you disabled capturing on the command line via pytest -s. In later versions, pytest automatically disables its output capture when you enter PDB tracing:

- · Output capture in other tests is not affected.
- Any prior test output that has already been captured and will be processed as such.
- Any later output produced within the same test will not be captured and will instead get sent directly to sys.stdout. Note that this holds true even for test output occurring after you exit the interactive PDB tracing session and continue with the regular test run.

Since pytest version 2.4.0 you can also use the native Python import pdb; pdb.set_trace() call to enter PDB tracing without having to use the pytest.set_trace() wrapper or explicitly disable pytest's output capturing via pytest -s.

2.8 Profiling test execution duration

To get a list of the slowest 10 test durations:

```
pytest --durations=10
```

2.9 Creating JUnitXML format files

To create result files which can be read by Jenkins or other Continuous integration servers, use this invocation:

```
pytest --junitxml=path
```

to create an XML file at path.

2.9.1 record_xml_property

New in version 2.8.

If you want to log additional information for a test, you can use the record_xml_property fixture:

```
def test_function(record_xml_property):
    record_xml_property("example_key", 1)
    assert 0
```

This will add an extra property example_key="1" to the generated testcase tag:

Warning: This is an experimental feature, and its interface might be replaced by something more powerful and general in future versions. The functionality per-se will be kept, however.

Currently it does not work when used with the pytest-xdist plugin.

Also please note that using this feature will break any schema verification. This might be a problem when used with some CI servers.

2.9.2 LogXML: add_global_property

New in version 3.0.

If you want to add a properties node in the testsuite level, which may contains properties that are relevant to all testcases you can use LogXML.add_global_properties

```
import pytest
@pytest.fixture(scope="session")
def log_global_env_facts(f):
    if pytest.config.pluginmanager.hasplugin('junitxml'):
        my_junit = getattr(pytest.config, '_xml', None)

    my_junit.add_global_property('ARCH', 'PPC')
    my_junit.add_global_property('STORAGE_TYPE', 'CEPH')

@pytest.mark.usefixtures(log_global_env_facts)
def start_and_prepare_env():
    pass

class TestMe:
    def test_foo(self):
        assert True
```

This will add a property node below the testsuite node to the generated xml:

Warning: This is an experimental feature, and its interface might be replaced by something more powerful and general in future versions. The functionality per-se will be kept.

2.10 Creating resultlog format files

Deprecated since version 3.0: This option is rarely used and is scheduled for removal in 4.0.

To create plain-text machine-readable result files you can issue:

```
pytest --resultlog=path
```

and look at the content at the path location. Such files are used e.g. by the PyPy-test web page to show test results over several revisions.

2.11 Sending test report to online pastebin service

Creating a URL for each test failure:

```
pytest --pastebin=failed
```

This will submit test run information to a remote Paste service and provide a URL for each failure. You may select tests as usual or add for example -x if you only want to send one particular failure.

Creating a URL for a whole test session log:

```
pytest --pastebin=all
```

Currently only pasting to the http://bpaste.net service is implemented.

2.12 Disabling plugins

To disable loading specific plugins at invocation time, use the -p option together with the prefix no:.

Example: to disable loading the plugin doctest, which is responsible for executing doctest tests from text files, invoke pytest like this:

```
pytest -p no:doctest
```

2.13 Calling pytest from Python code

New in version 2.0.

You can invoke pytest from Python code directly:

```
pytest.main()
```

this acts as if you would call "pytest" from the command line. It will not raise SystemExit but return the exitcode instead. You can pass in options and arguments:

```
pytest.main(['-x', 'mytestdir'])
```

or pass in a string:

```
pytest.main("-x mytestdir")
```

You can specify additional plugins to pytest.main:

```
# content of myinvoke.py
import pytest
class MyPlugin:
    def pytest_sessionfinish(self):
        print("*** test run reporting finishing")

pytest.main(["-qq"], plugins=[MyPlugin()])
```

Running it will show that MyPlugin was added and its hook was invoked:

\$ python myinvoke.py
*** test run reporting finishing

The writing and reporting of assertions in tests

3.1 Asserting with the assert statement

pytest allows you to use the standard python assert for verifying expectations and values in Python tests. For example, you can write the following:

```
# content of test_assert1.py
def f():
    return 3

def test_function():
    assert f() == 4
```

to assert that your function returns a certain value. If this assertion fails you will see the return value of the function call:

pytest has support for showing the values of the most common subexpressions including calls, attributes, comparisons, and binary and unary operators. (See *Demo of Python failure reports with pytest*). This allows you to use the idiomatic python constructs without boilerplate code while not losing introspection information.

However, if you specify a message with the assertion like this:

```
assert a % 2 == 0, "value was odd, should be even"
```

then no assertion introspection takes places at all and the message will be simply shown in the traceback.

See Advanced assertion introspection for more information on assertion introspection.

3.2 Assertions about expected exceptions

In order to write assertions about raised exceptions, you can use pytest.raises as a context manager like this:

and if you need to have access to the actual exception info you may use:

excinfo is a ExceptionInfo instance, which is a wrapper around the actual exception raised. The main attributes of interest are .type, .value and .traceback.

Changed in version 3.0.

In the context manager form you may use the keyword argument message to specify a custom failure message:

```
>>> with raises(ZeroDivisionError, message="Expecting ZeroDivisionError"):
... pass
... Failed: Expecting ZeroDivisionError
```

If you want to write test code that works on Python 2.4 as well, you may also use two other ways to test for an expected exception:

```
pytest.raises(ExpectedException, func, *args, **kwargs)
pytest.raises(ExpectedException, "func(*args, **kwargs)")
```

both of which execute the specified function with args and kwargs and asserts that the given ExpectedException is raised. The reporter will provide you with helpful output in case of failures such as *no exception* or *wrong exception*.

Note that it is also possible to specify a "raises" argument to pytest.mark.xfail, which checks that the test is failing in a more specific way than just having any exception raised:

```
@pytest.mark.xfail(raises=IndexError)
def test_f():
    f()
```

Using pytest.raises is likely to be better for cases where you are testing exceptions your own code is deliberately raising, whereas using <code>@pytest.mark.xfail</code> with a check function is probably better for something like documenting unfixed bugs (where the test describes what "should" happen) or bugs in dependencies.

If you want to test that a regular expression matches on the string representation of an exception (like the TestCase.assertRaisesRegexp method from unittest) you can use the ExceptionInfo.match method:

```
import pytest
def myfunc():
```

```
raise ValueError("Exception 123 raised")

def test_match():
    with pytest.raises(ValueError) as excinfo:
        myfunc()
    excinfo.match(r'.* 123 .*')
```

The regexp parameter of the match method is matched with the re.search function. So in the above example excinfo.match('123') would have worked as well.

3.3 Assertions about expected warnings

New in version 2.8.

You can check that code raises a particular warning using *pytest.warns*.

3.4 Making use of context-sensitive comparisons

New in version 2.0.

pytest has rich support for providing context-sensitive information when it encounters comparisons. For example:

```
# content of test_assert2.py

def test_set_comparison():
    set1 = set("1308")
    set2 = set("8035")
    assert set1 == set2
```

if you run this module:

```
$ pytest test_assert2.py
====== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 1 items
test_assert2.py F
====== FAILURES ======
     __ test_set_comparison _
   def test_set_comparison():
       set1 = set("1308")
       set2 = set("8035")
       assert set1 == set2
       assert {'0', '1', '3', '8'} == {'0', '3', '5', '8'}
Ε
         Extra items in the left set:
Ε
Ε
         Extra items in the right set:
Ε
         Use -v to get the full diff
test_assert2.py:5: AssertionError
====== 1 failed in 0.12 seconds ======
```

Special comparisons are done for a number of cases:

- · comparing long strings: a context diff is shown
- comparing long sequences: first failing indices
- comparing dicts: different entries

See the *reporting demo* for many more examples.

3.5 Defining your own assertion comparison

It is possible to add your own detailed explanations by implementing the pytest_assertrepr_compare hook.

```
pytest_assertrepr_compare (config, op, left, right)
```

return explanation for comparisons in failing assert expressions.

Return None for no custom explanation, otherwise return a list of strings. The strings will be joined by newlines but any newlines *in* a string will be escaped. Note that all but the first line will be indented sligthly, the intention is for the first line to be a summary.

As an example consider adding the following hook in a conftest.py which provides an alternative explanation for Foo objects:

now, given this test module:

```
# content of test_foocompare.py
class Foo:
    def __init__(self, val):
        self.val = val

    def __eq__(self, other):
        return self.val == other.val

def test_compare():
    f1 = Foo(1)
    f2 = Foo(2)
    assert f1 == f2
```

you can run the test module and get the custom output defined in the conftest file:

```
test_foocompare.py:11: AssertionError
1 failed in 0.12 seconds
```

3.6 Advanced assertion introspection

New in version 2.1.

Reporting details about a failing assertion is achieved either by rewriting assert statements before they are run or re-evaluating the assert expression and recording the intermediate values. Which technique is used depends on the location of the assert, pytest configuration, and Python version being used to run pytest.

By default, pytest rewrites assert statements in test modules. Rewritten assert statements put introspection information into the assertion failure message. pytest only rewrites test modules directly discovered by its test collection process, so asserts in supporting modules which are not themselves test modules will not be rewritten.

Note: pytest rewrites test modules on import. It does this by using an import hook to write a new pyc files. Most of the time this works transparently. However, if you are messing with import yourself, the import hook may interfere. If this is the case, simply use --assert=reinterp or --assert=plain. Additionally, rewriting will fail silently if it cannot write new pycs, i.e. in a read-only filesystem or a zipfile.

If an assert statement has not been rewritten or the Python version is less than 2.6, pytest falls back on assert reinterpretation. In assert reinterpretation, pytest walks the frame of the function containing the assert statement to discover sub-expression results of the failing assert statement. You can force pytest to always use assertion reinterpretation by passing the --assert=reinterp option.

Assert reinterpretation has a caveat not present with assert rewriting: If evaluating the assert expression has side effects you may get a warning that the intermediate values could not be determined safely. A common example of this issue is an assertion which reads from a file:

```
assert f.read() != '...'
```

If this assertion fails then the re-evaluation will probably succeed! This is because f.read() will return an empty string when it is called the second time during the re-evaluation. However, it is easy to rewrite the assertion and avoid any trouble:

```
content = f.read()
assert content != '...'
```

All assert introspection can be turned off by passing --assert=plain.

For further information, Benjamin Peterson wrote up Behind the scenes of pytest's new assertion rewriting.

New in version 2.1: Add assert rewriting as an alternate introspection technique.

Changed in version 2.1: Introduce the --assert option. Deprecate --no-assert and --nomagic.

Changed in version 3.0: Removes the --no-assert and '-nomagic' options.

Pytest API and builtin fixtures

This is a list of pytest. * API functions and fixtures.

For information on plugin hooks and objects, see Writing plugins.

For information on the pytest.mark mechanism, see Marking test functions with attributes.

For the below objects, you can also interactively ask for help, e.g. by typing on the Python interactive prompt something like:

```
import pytest
help(pytest)
```

4.1 Invoking pytest interactively

main (args=None, plugins=None)
return exit code, after performing an in-process test run.

Parameters

- args list of command line arguments.
- plugins list of plugin objects to be auto-registered during initialization.

More examples at Calling pytest from Python code

4.2 Helpers for assertions about Exceptions/Warnings

```
raises (expected_exception, *args, **kwargs)
```

Assert that a code block/function call raises expected_exception and raise a failure exception otherwise.

This helper produces a ExceptionInfo() object (see below).

If using Python 2.5 or above, you may use this function as a context manager:

```
>>> with raises(ZeroDivisionError):
... 1/0
```

Changed in version 2.10.

In the context manager form you may use the keyword argument message to specify a custom failure message:

```
>>> with raises(ZeroDivisionError, message="Expecting ZeroDivisionError"):
... pass
... Failed: Expecting ZeroDivisionError
```

Note: When using pytest.raises as a context manager, it's worthwhile to note that normal context manager rules apply and that the exception raised *must* be the final line in the scope of the context manager. Lines of code after that, within the scope of the context manager will not be executed. For example:

```
>>> with raises(OSError) as exc_info:
    assert 1 == 1 # this will execute as expected
    raise OSError(errno.EEXISTS, 'directory exists')
    assert exc_info.value.errno == errno.EEXISTS # this will not execute
```

Instead, the following approach must be taken (note the difference in scope):

```
>>> with raises(OSError) as exc_info:
    assert 1 == 1 # this will execute as expected
    raise OSError(errno.EEXISTS, 'directory exists')

assert exc_info.value.errno == errno.EEXISTS # this will now execute
```

Or you can specify a callable by passing a to-be-called lambda:

```
>>> raises(ZeroDivisionError, lambda: 1/0)
<ExceptionInfo ...>
```

or you can specify an arbitrary callable with arguments:

```
>>> def f(x): return 1/x
...
>>> raises(ZeroDivisionError, f, 0)
<ExceptionInfo ...>
>>> raises(ZeroDivisionError, f, x=0)
<ExceptionInfo ...>
```

A third possibility is to use a string to be executed:

```
>>> raises(ZeroDivisionError, "f(0)")
<ExceptionInfo ...>
```

```
class ExceptionInfo (tup=None, exprinfo=None)
```

wraps sys.exc_info() objects and offers help for navigating the traceback.

```
type = None
```

the exception class

value = None

the exception instance

tb = None

the exception raw traceback

typename = None

the exception type name

traceback = None

the exception traceback (_pytest._code.Traceback instance)

```
exconly (tryshort=False)
```

return the exception as a string

when 'tryshort' resolves to True, and the exception is a _pytest._code._AssertionError, only the actual exception part of the exception representation is returned (so 'AssertionError: ' is removed from the beginning)

```
errisinstance(exc)
```

return True if the exception is an instance of exc

getrepr (showlocals=False, style='long', abspath=False, tbfilter=True, funcargs=False)
return str()able representation of this exception info. showlocals: show locals per traceback entry
style: longlshortlnolnative traceback style tbfilter: hide entries (where __tracebackhide__ is true)

in case of style==native, tbfilter and showlocals is ignored.

match (regexp)

Match the regular expression 'regexp' on the string representation of the exception. If it matches then True is returned (so that it is possible to write 'assert excinfo.match()'). If it doesn't match an AssertionError is raised.

Note: Similar to caught exception objects in Python, explicitly clearing local references to returned ExceptionInfo objects can help the Python interpreter speed up its garbage collection.

Clearing those references breaks a reference cycle (ExceptionInfo -> caught exception -> frame stack raising the exception -> current frame stack -> local variables -> ExceptionInfo) which makes Python keep all objects referenced from that cycle (including all local variables in the current frame) alive until the next cyclic garbage collection run. See the official Python try statement documentation for more detailed information.

Examples at Assertions about expected exceptions.

```
deprecated_call (func=None, *args, **kwargs)
```

assert that calling func(*args, **kwargs) triggers a DeprecationWarning or PendingDeprecationWarning.

This function can be used as a context manager:

```
>>> with deprecated_call():
... myobject.deprecated_method()
```

Note: we cannot use WarningsRecorder here because it is still subject to the mechanism that prevents warnings of the same type from being triggered twice for the same module. See #1190.

4.3 Comparing floating point numbers

class approx (expected, rel=None, abs=None)

Assert that two numbers (or two sets of numbers) are equal to each other within some tolerance.

Due to the intricacies of floating-point arithmetic, numbers that we would intuitively expect to be equal are not always so:

```
>>> 0.1 + 0.2 == 0.3
False
```

This problem is commonly encountered when writing tests, e.g. when making sure that floating-point values are what you expect them to be. One way to deal with this problem is to assert that two floating-point numbers are equal to within some appropriate tolerance:

```
>>> abs((0.1 + 0.2) - 0.3) < 1e-6
True
```

However, comparisons like this are tedious to write and difficult to understand. Furthermore, absolute comparisons like the one above are usually discouraged because there's no tolerance that works well for all situations. 1e-6 is good for numbers around 1, but too small for very big numbers and too big for very small ones. It's better to express the tolerance as a fraction of the expected value, but relative comparisons like that are even more difficult to write correctly and concisely.

The approx class performs floating-point comparisons using a syntax that's as intuitive as possible:

```
>>> from pytest import approx
>>> 0.1 + 0.2 == approx(0.3)
True
```

The same syntax also works on sequences of numbers:

```
>>> (0.1 + 0.2, 0.2 + 0.4) == approx((0.3, 0.6))
True
```

By default, approx considers numbers within a relative tolerance of 1e-6 (i.e. one part in a million) of its expected value to be equal. This treatment would lead to surprising results if the expected value was 0.0, because nothing but 0.0 itself is relatively close to 0.0. To handle this case less surprisingly, approx also considers numbers within an absolute tolerance of 1e-12 of its expected value to be equal. Infinite numbers are another special case. They are only considered equal to themselves, regardless of the relative tolerance. Both the relative and absolute tolerances can be changed by passing arguments to the approx constructor:

```
>>> 1.0001 == approx(1)
False
>>> 1.0001 == approx(1, rel=1e-3)
True
>>> 1.0001 == approx(1, abs=1e-3)
True
```

If you specify abs but not rel, the comparison will not consider the relative tolerance at all. In other words, two numbers that are within the default relative tolerance of 1e-6 will still be considered unequal if they exceed the specified absolute tolerance. If you specify both abs and rel, the numbers will be considered equal if either tolerance is met:

```
>>> 1 + 1e-8 == approx(1)
True
>>> 1 + 1e-8 == approx(1, abs=1e-12)
False
>>> 1 + 1e-8 == approx(1, rel=1e-6, abs=1e-12)
True
```

If you're thinking about using approx, then you might want to know how it compares to other good ways of comparing floating-point numbers. All of these algorithms are based on relative and absolute tolerances and should agree for the most part, but they do have meaningful differences:

•math.isclose(a, b, rel_tol=1e-9, abs_tol=0.0): True if the relative tolerance is met w.r.t. either a or b or if the absolute tolerance is met. Because the relative tolerance is calculated w.r.t. both a and b, this test is symmetric (i.e. neither a nor b is a "reference value"). You have to specify an absolute tolerance if you want to compare to 0.0 because there is no tolerance by default. Only available in python>=3.5. More information...

- •numpy.isclose(a, b, rtol=1e-5, atol=1e-8): True if the difference between a and b is less that the sum of the relative tolerance w.r.t. b and the absolute tolerance. Because the relative tolerance is only calculated w.r.t. b, this test is asymmetric and you can think of b as the reference value. Support for comparing sequences is provided by numpy.allclose. More information...
- •unittest.TestCase.assertAlmostEqual (a, b): True if a and b are within an absolute tolerance of 1e-7. No relative tolerance is considered and the absolute tolerance cannot be changed, so this function is not appropriate for very large or very small numbers. Also, it's only available in subclasses of unittest.TestCase and it's ugly because it doesn't follow PEP8. More information...
- •a == pytest.approx(b, rel=1e-6, abs=1e-12): True if the relative tolerance is met w.r.t. b or if the absolute tolerance is met. Because the relative tolerance is only calculated w.r.t. b, this test is asymmetric and you can think of b as the reference value. In the special case that you explicitly specify an absolute tolerance but not a relative tolerance, only the absolute tolerance is considered.

4.4 Raising a specific test outcome

You can use the following functions in your test, fixture or setup functions to force a certain test outcome. Note that most often you can rather use declarative marks, see *Skip and xfail: dealing with tests that can not succeed*.

```
fail (msg='', pytrace=True)
```

explicitly fail an currently-executing test with the given Message.

Parameters pytrace – if false the msg represents the full failure information and no python trace-back will be reported.

```
skip (msg='')
```

skip an executing test with the given message. Note: it's usually better to use the pytest.mark.skipif marker to declare a test to be skipped under certain conditions like mismatching platforms or dependencies. See the pytest_skipping plugin for details.

```
importorskip (modname, minversion=None)
```

return imported module if it has at least "minversion" as its __version__ attribute. If no minversion is specified the a skip is only triggered if the module can not be imported.

```
xfail (reason='')
```

xfail an executing test or setup functions with the given reason.

exit (msg)

exit testing process as if KeyboardInterrupt was triggered.

4.5 Fixtures and requests

To mark a fixture function:

```
fixture (scope='function', params=None, autouse=False, ids=None, name=None) (return a) decorator to mark a fixture factory function.
```

This decorator can be used (with or or without parameters) to define a fixture function. The name of the fixture function can later be referenced to cause its invocation ahead of running tests: test modules or classes can use the pytest.mark.usefixtures(fixturename) marker. Test functions can directly use fixture names as input arguments in which case the fixture instance returned from the fixture function will be injected.

Parameters

• **scope** – the scope for which this fixture is shared, one of "function" (default), "class", "module" or "session".

- params an optional list of parameters which will cause multiple invocations of the fixture function and all of the tests using it.
- **autouse** if True, the fixture func is activated for all tests that can see it. If False (the default) then an explicit reference is needed to activate the fixture.
- ids list of string ids each corresponding to the params so that they are part of the test id. If no ids are provided they will be generated automatically from the params.
- name the name of the fixture. This defaults to the name of the decorated function. If a fixture is used in the same module in which it is defined, the function name of the fixture will be shadowed by the function arg that requests the fixture; one way to resolve this is to name the decorated function fixture_<fixturename> and then use @pytest.fixture(name='<fixturename>').

Fixtures can optionally provide their values to test functions using a yield statement, instead of return. In this case, the code block after the yield statement is executed as teardown code regardless of the test outcome. A fixture function must yield exactly once.

Tutorial at pytest fixtures: explicit, modular, scalable.

The request object that can be used from fixture functions.

class FixtureRequest

A request for a fixture from a test or fixture function.

A request object gives access to the requesting test context and has an optional param attribute in case the fixture is parametrized indirectly.

fixturename = None

fixture for which this request is being performed

scope = None

Scope string, one of "function", "class", "module", "session"

node

underlying collection node (depends on current request scope)

confid

the pytest config object associated with this request.

function

test function object if the request has a per-function scope.

cls

class (can be None) where the test function was collected.

instance

instance (can be None) on which test function was collected.

module

python module object where the test function was collected.

fspath

the file system path of the test module which collected this test.

keywords

keywords/markers dictionary for the underlying node.

session

pytest session object.

addfinalizer (finalizer)

add finalizer/teardown function to be called after the last test within the requesting test context finished execution.

applymarker (marker)

Apply a marker to a single test function invocation. This method is useful if you don't want to have a keyword/marker on all function invocations.

```
Parameters marker – a _pytest.mark.MarkDecorator object created by a call to pytest.mark.NAME(...).
```

raiseerror (msg)

raise a FixtureLookupError with the given message.

```
cached_setup (setup, teardown=None, scope='module', extrakey=None)
```

(deprecated) Return a testing resource managed by setup & teardown calls. scope and extrakey determine when the teardown function will be called so that subsequent calls to setup would recreate the resource. With pytest-2.3 you often do not need cached_setup() as you can directly declare a scope on a fixture function and register a finalizer through request.addfinalizer().

Parameters

- **teardown** function receiving a previously setup resource.
- **setup** a no-argument function creating a resource.
- **scope** a string value out of function, class, module or session indicating the caching lifecycle of the resource.
- extrakey added to internal caching key of (funcargname, scope).

getfixturevalue(argname)

Dynamically run a named fixture function.

Declaring fixtures via function argument is recommended where possible. But if you can only decide whether to use another fixture at test setup time, you may use this function to retrieve it inside a fixture or test function body.

getfuncarqvalue(argname)

Deprecated, use getfixturevalue.

4.6 Builtin fixtures/function arguments

You can ask for available builtin or project-custom *fixtures* by typing:

```
$ pytest -q --fixtures
cache
Return a cache object that can persist state between testing sessions.

cache.get(key, default)
cache.set(key, value)

Keys must be a ``/`` separated value, where the first part is usually the name of your plugin or application to avoid clashes with other cache users.

Values can be any object handled by the json stdlib module.
capsys
    Enable capturing of writes to sys.stdout/sys.stderr and make captured output available via ``capsys.readouterr()`` method calls which return a ``(out, err)`` tuple.
```

```
capfd
   Enable capturing of writes to file descriptors 1 and 2 and make
    captured output available via ``capfd.readouterr()`` method calls
    which return a ``(out, err)`` tuple.
doctest_namespace
    Inject names into the doctest namespace.
pytestconfig
   the pytest config object with access to command line opts.
record_xml_property
   Add extra xml properties to the tag for the calling test.
   The fixture is callable with ``(name, value)``, with value being automatically
monkeypatch
   The returned ``monkeypatch`` fixture provides these
   helper methods to modify objects, dictionaries or os.environ::
   monkeypatch.setattr(obj, name, value, raising=True)
   monkeypatch.delattr(obj, name, raising=True)
   monkeypatch.setitem(mapping, name, value)
   monkeypatch.delitem(obj, name, raising=True)
   monkeypatch.setenv(name, value, prepend=False)
   monkeypatch.delenv(name, value, raising=True)
   monkeypatch.syspath_prepend(path)
   monkeypatch.chdir(path)
   All modifications will be undone after the requesting
   test function or fixture has finished. The ``raising`
   parameter determines if a KeyError or AttributeError
   will be raised if the set/deletion operation has no target.
recwarn
   Return a WarningsRecorder instance that provides these methods:
    \star ``pop(category=None)``: return last warning matching the category.
    * ``clear()``: clear list of warnings
   See http://docs.python.org/library/warnings.html for information
   on warning categories.
tmpdir_factory
   Return a TempdirFactory instance for the test session.
t.mpdir
   Return a temporary directory path object
   which is unique to each test function invocation,
   created as a sub directory of the base temporary
   directory. The returned object is a `py.path.local`_
   path object.
no tests ran in 0.12 seconds
```

pytest fixtures: explicit, modular, scalable

New in version 2.0/2.3/2.4.

The purpose of test fixtures is to provide a fixed baseline upon which tests can reliably and repeatedly execute. pytest fixtures offer dramatic improvements over the classic xUnit style of setup/teardown functions:

- fixtures have explicit names and are activated by declaring their use from test functions, modules, classes or whole projects.
- fixtures are implemented in a modular manner, as each fixture name triggers a *fixture function* which can itself use other fixtures.
- fixture management scales from simple unit to complex functional testing, allowing to parametrize fixtures and tests according to configuration and component options, or to re-use fixtures across class, module or whole test session scopes.

In addition, pytest continues to support *classic xunit-style setup*. You can mix both styles, moving incrementally from classic to new style, as you prefer. You can also start out from existing *unittest.TestCase style* or *nose based* projects.

5.1 Fixtures as Function arguments

Test functions can receive fixture objects by naming them as an input argument. For each argument name, a fixture function with that name provides the fixture object. Fixture functions are registered by marking them with @pytest.fixture. Let's look at a simple self-contained test module containing a fixture and a test function using it:

```
# content of ./test_smtpsimple.py
import pytest

@pytest.fixture
def smtp():
    import smtplib
    return smtplib.SMTP("smtp.gmail.com")

def test_ehlo(smtp):
    response, msg = smtp.ehlo()
    assert response == 250
    assert 0 # for demo purposes
```

Here, the test_ehlo needs the smtp fixture value. pytest will discover and call the @pytest.fixture marked smtp fixture function. Running the test looks like this:

```
$ pytest test_smtpsimple.py
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 1 items
test_smtpsimple.py F
====== FAILURES ======
  _____ test_ehlo _____
smtp = <smtplib.SMTP object at 0xdeadbeef>
   def test_ehlo(smtp):
       response, msg = smtp.ehlo()
       assert response == 250
       assert 0 # for demo purposes
       assert 0
test_smtpsimple.py:11: AssertionError
====== 1 failed in 0.12 seconds ======
```

In the failure traceback we see that the test function was called with a smtp argument, the smtplib.SMTP() instance created by the fixture function. The test function fails on our deliberate assert 0. Here is the exact protocol used by pytest to call the test function this way:

- 1. pytest *finds* the test_ehlo because of the test_prefix. The test function needs a function argument named smtp. A matching fixture function is discovered by looking for a fixture-marked function named smtp.
- 2. smtp() is called to create an instance.
- 3. test_ehlo(<SMTP instance>) is called and fails in the last line of the test function.

Note that if you misspell a function argument or want to use one that isn't available, you'll see an error with a list of available function arguments.

Note: You can always issue:

```
pytest --fixtures test_simplefactory.py
```

to see available fixtures.

In versions prior to 2.3 there was no @pytest.fixture marker and you had to use a magic pytest_funcarg__NAME prefix for the fixture factory. This remains and will remain supported but is not anymore advertised as the primary means of declaring fixture functions.

5.2 "Funcargs" a prime example of dependency injection

When injecting fixtures to test functions, pytest-2.0 introduced the term "funcargs" or "funcarg mechanism" which continues to be present also in docs today. It now refers to the specific case of injecting fixture values as arguments to test functions. With pytest-2.3 there are more possibilities to use fixtures but "funcargs" remain as the main way as they allow to directly state the dependencies of a test function.

As the following examples show in more detail, funcargs allow test functions to easily receive and work against specific pre-initialized application objects without having to care about import/setup/cleanup details. It's a prime example of

dependency injection where fixture functions take the role of the *injector* and test functions are the *consumers* of fixture objects.

5.3 Sharing a fixture across tests in a module (or class/session)

Fixtures requiring network access depend on connectivity and are usually time-expensive to create. Extending the previous example, we can add a scope='module' parameter to the @pytest.fixture invocation to cause the decorated smtp fixture function to only be invoked once per test module. Multiple test functions in a test module will thus each receive the same smtp fixture instance. The next example puts the fixture function into a separate conftest.py file so that tests from multiple test modules in the directory can access the fixture function:

```
# content of conftest.py
import pytest
import smtplib

@pytest.fixture(scope="module")
def smtp():
    return smtplib.SMTP("smtp.gmail.com")
```

The name of the fixture again is smtp and you can access its result by listing the name smtp as an input parameter in any test or fixture function (in or below the directory where conftest.py is located):

```
# content of test_module.py

def test_ehlo(smtp):
    response, msg = smtp.ehlo()
    assert response == 250
    assert b"smtp.gmail.com" in msg
    assert 0 # for demo purposes

def test_noop(smtp):
    response, msg = smtp.noop()
    assert response == 250
    assert 0 # for demo purposes
```

We deliberately insert failing assert 0 statements in order to inspect what is going on and can now run the tests:

```
$ pytest test_module.py
======= test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items

test_module.py FF
====== FAILURES =======
_____ test_ehlo ____

smtp = <smtplib.SMTP object at 0xdeadbeef>

def test_ehlo(smtp):
    response, msg = smtp.ehlo()
    assert response == 250
    assert b"smtp.gmail.com" in msg
> assert 0 # for demo purposes
E assert 0
```

You see the two assert 0 failing and more importantly you can also see that the same (module-scoped) smtp object was passed into the two test functions because pytest shows the incoming argument values in the traceback. As a result, the two test functions using smtp run as quick as a single one because they reuse the same instance.

If you decide that you rather want to have a session-scoped smtp instance, you can simply declare it:

```
@pytest.fixture(scope="session")
def smtp(...):
    # the returned fixture value will be shared for
    # all tests needing it
```

5.4 Fixture finalization / executing teardown code

pytest supports execution of fixture specific finalization code when the fixture goes out of scope. By using a yield statement instead of return, all the code after the *yield* statement serves as the teardown code.:

```
# content of conftest.py
import smtplib
import pytest

@pytest.fixture(scope="module")
def smtp(request):
    smtp = smtplib.SMTP("smtp.gmail.com")
    yield smtp # provide the fixture value
    print("teardown smtp")
    smtp.close()
```

The print and smtp.close() statements will execute when the last test using the fixture in the module has finished execution, regardless of the exception status of the tests.

Let's execute it:

```
$ pytest -s -q --tb=no
FFteardown smtp
2 failed in 0.12 seconds
```

We see that the smtp instance is finalized after the two tests finished execution. Note that if we decorated our fixture function with scope='function' then fixture setup and cleanup would occur around each single test. In either case the test module itself does not need to change or know about these details of fixture setup.

Note that we can also seamlessly use the yield syntax with with statements:

```
# content of test_yield2.py
import pytest
@pytest.fixture
def passwd():
    with open("/etc/passwd") as f:
        yield f.readlines()

def test_has_lines(passwd):
    assert len(passwd) >= 1
```

The file f will be closed after the test finished execution because the Python file object supports finalization when the with statement ends.

Note: Prior to version 2.10, in order to use a yield statement to execute teardown code one had to mark a fixture using the yield_fixture marker. From 2.10 onward, normal fixtures can use yield directly so the yield_fixture decorator is no longer needed and considered deprecated.

Note: As historical note, another way to write teardown code is by accepting a request object into your fixture function and can call its request.addfinalizer one or multiple times:

```
# content of conftest.py
import smtplib
import pytest

@pytest.fixture(scope="module")
def smtp(request):
    smtp = smtplib.SMTP("smtp.gmail.com")
    def fin():
        print ("teardown smtp")
        smtp.close()
    request.addfinalizer(fin)
    return smtp # provide the fixture value
```

The fin function will execute when the last test using the fixture in the module has finished execution.

This method is still fully supported, but yield is recommended from 2.10 onward because it is considered simpler and better describes the natural code flow.

5.5 Fixtures can introspect the requesting test context

Fixture function can accept the request object to introspect the "requesting" test function, class or module context. Further extending the previous smtp fixture example, let's read an optional server URL from the test module which uses our fixture:

```
# content of conftest.py
import pytest
import smtplib

@pytest.fixture(scope="module")
def smtp(request):
```

```
server = getattr(request.module, "smtpserver", "smtp.gmail.com")
smtp = smtplib.SMTP(server)
yield smtp
print ("finalizing %s (%s)" % (smtp, server))
smtp.close()
```

We use the request .module attribute to optionally obtain an smtpserver attribute from the test module. If we just execute again, nothing much has changed:

```
$ pytest -s -q --tb=no
FFfinalizing <smtplib.SMTP object at 0xdeadbeef> (smtp.gmail.com)
.
2 failed, 1 passed in 0.12 seconds
```

Let's quickly create another test module that actually sets the server URL in its module namespace:

```
# content of test_anothersmtp.py
smtpserver = "mail.python.org" # will be read by smtp fixture

def test_showhelo(smtp):
    assert 0, smtp.helo()
```

Running it:

```
$ pytest -qq --tb=short test_anothersmtp.py
F
====== FAILURES ======
_____ test_showhelo ____
test_anothersmtp.py:5: in test_showhelo
    assert 0, smtp.helo()
E AssertionError: (250, b'mail.python.org')
E assert 0
```

voila! The smtp fixture function picked up our mail server name from the module namespace.

5.6 Parametrizing fixtures

Fixture functions can be parametrized in which case they will be called multiple times, each time executing the set of dependent tests, i. e. the tests that depend on this fixture. Test functions do usually not need to be aware of their re-running. Fixture parametrization helps to write exhaustive functional tests for components which themselves can be configured in multiple ways.

Extending the previous example, we can flag the fixture to create two smtp fixture instances which will cause all tests using the fixture to run twice. The fixture function gets access to each parameter through the special request object:

The main change is the declaration of params with @pytest.fixture, a list of values for each of which the fixture function will execute and can access a value via request.param. No test function code needs to change. So let's just do another run:

```
$ pytest -q test_module.py
FFFF
====== FAILURES ======
   ____ test_ehlo[smtp.gmail.com] ____
smtp = <smtplib.SMTP object at 0xdeadbeef>
   def test_ehlo(smtp):
       response, msg = smtp.ehlo()
       assert response == 250
       assert b"smtp.gmail.com" in msg
       assert 0 # for demo purposes
       assert 0
test_module.py:6: AssertionError
 _____ test_noop[smtp.gmail.com] _
smtp = <smtplib.SMTP object at 0xdeadbeef>
   def test_noop(smtp):
       response, msg = smtp.noop()
       assert response == 250
       assert 0 # for demo purposes
       assert 0
test_module.py:11: AssertionError
_____ test_ehlo[mail.python.org] ____
smtp = <smtplib.SMTP object at 0xdeadbeef>
   def test_ehlo(smtp):
       response, msg = smtp.ehlo()
       assert response == 250
       assert b"smtp.gmail.com" in msg
       assert b'smtp.gmail.com' in b'mail.python.org\nSIZE 51200000\nETRN\nSTARTTLS\nENHANCEDSTATUS
Ε
test_module.py:5: AssertionError
----- Captured stdout setup ------
finalizing <smtplib.SMTP object at 0xdeadbeef>
   ____ test_noop[mail.python.org] ___
smtp = <smtplib.SMTP object at 0xdeadbeef>
   def test_noop(smtp):
       response, msg = smtp.noop()
       assert response == 250
       assert 0 # for demo purposes
Ε
       assert 0
test_module.py:11: AssertionError
4 failed in 0.12 seconds
```

We see that our two test functions each ran twice, against the different smtp instances. Note also, that with the mail.python.org connection the second test fails in test_ehlo because a different server string is expected than what arrived.

pytest will build a string that is the test ID for each fixture value in a parametrized fixture, e.g. test_ehlo[smtp.gmail.com] and test_ehlo[mail.python.org] in the above examples. These IDs can be used with -k to select specific cases to run, and they will also identify the specific case when one is failing. Running pytest with --collect-only will show the generated IDs.

Numbers, strings, booleans and None will have their usual string representation used in the test ID. For other objects, pytest will make a string based on the argument name. It is possible to customise the string used in a test ID for a certain fixture value by using the ids keyword argument:

```
# content of test_ids.py
import pytest
@pytest.fixture(params=[0, 1], ids=["spam", "ham"])
def a(request):
    return request.param
def test_a(a):
   pass
def idfn(fixture_value):
    if fixture_value == 0:
        return "eggs"
    else:
        return None
@pytest.fixture(params=[0, 1], ids=idfn)
def b(request):
    return request.param
def test_b(b):
    pass
```

The above shows how ids can be either a list of strings to use or a function which will be called with the fixture value and then has to return a string to use. In the latter case if the function return None then pytest's auto-generated ID will be used.

Running the above tests results in the following test IDs being used:

```
$ pytest --collect-only
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1

```

5.7 Modularity: using fixtures from a fixture function

You can not only use fixtures in test functions but fixture functions can use other fixtures themselves. This contributes to a modular design of your fixtures and allows re-use of framework-specific fixtures across many projects. As a simple example, we can extend the previous example and instantiate an object app where we stick the already defined smtp resource into it:

```
# content of test_appsetup.py
import pytest

class App:
    def __init__(self, smtp):
        self.smtp = smtp

@pytest.fixture(scope="module")
def app(smtp):
    return App(smtp)

def test_smtp_exists(app):
    assert app.smtp
```

Here we declare an app fixture which receives the previously defined smtp fixture and instantiates an App object with it. Let's run it:

```
$ pytest -v test_appsetup.py
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.5
cachedir: .cache
rootdir: $REGENDOC_TMPDIR, inifile:
collecting ... collected 2 items

test_appsetup.py::test_smtp_exists[smtp.gmail.com] PASSED
test_appsetup.py::test_smtp_exists[mail.python.org] PASSED
========= 2 passed in 0.12 seconds =========
```

Due to the parametrization of smtp the test will run twice with two different App instances and respective smtp servers. There is no need for the app fixture to be aware of the smtp parametrization as pytest will fully analyse the fixture dependency graph.

Note, that the app fixture has a scope of module and uses a module-scoped smtp fixture. The example would still work if smtp was cached on a session scope: it is fine for fixtures to use "broader" scoped fixtures but not the other way round: A session-scoped fixture could not use a module-scoped one in a meaningful way.

5.8 Automatic grouping of tests by fixture instances

pytest minimizes the number of active fixtures during test runs. If you have a parametrized fixture, then all the tests using it will first execute with one instance and then finalizers are called before the next fixture instance is created. Among other things, this eases testing of applications which create and use global state.

The following example uses two parametrized fixture, one of which is scoped on a per-module basis, and all the functions perform print calls to show the setup/teardown flow:

```
# content of test_module.py
import pytest
@pytest.fixture(scope="module", params=["mod1", "mod2"])
def modarg(request):
   param = request.param
   print (" SETUP modarg %s" % param)
   yield param
   print (" TEARDOWN modarg %s" % param)
@pytest.fixture(scope="function", params=[1,2])
def otherarg(request):
   param = request.param
   print (" SETUP otherarg %s" % param)
   yield param
   print (" TEARDOWN otherarg %s" % param)
def test_0 (otherarg):
   print (" RUN test0 with otherarg %s" % otherarg)
def test_1 (modarg):
   print (" RUN test1 with modarg %s" % modarg)
def test_2 (otherarg, modarg):
   print (" RUN test2 with otherarg %s and modarg %s" % (otherarg, modarg))
```

Let's run the tests in verbose mode and with looking at the print-output:

```
$ pytest -v -s test_module.py
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.
cachedir: .cache
rootdir: $REGENDOC_TMPDIR, inifile:
collecting ... collected 8 items
RUN test0 with otherarg 1
PASSED TEARDOWN otherarg 1
RUN test0 with otherarg 2
PASSED TEARDOWN otherarg 2
RUN test1 with modarg mod1
PASSED
RUN test2 with otherarg 1 and modarg mod1
PASSED TEARDOWN otherarg 1
test_module.py::test_2[2-mod1]
                      SETUP otherarg 2
 RUN test2 with otherarg 2 and modarg mod1
PASSED TEARDOWN otherarg 2
SETUP modarg mod2
 RUN test1 with modarg mod2
PASSED
```

You can see that the parametrized module-scoped modarg resource caused an ordering of test execution that lead to the fewest possible "active" resources. The finalizer for the mod1 parametrized resource was executed before the mod2 resource was setup.

In particular notice that test_0 is completely independent and finishes first. Then test_1 is executed with mod1, then test_2 with mod1, then test_1 with mod2 and finally test_2 with mod2.

The otherarg parametrized resource (having function scope) was set up before and teared down after every test that used it.

5.9 Using fixtures from classes, modules or projects

Sometimes test functions do not directly need access to a fixture object. For example, tests may require to operate with an empty directory as the current working directory but otherwise do not care for the concrete directory. Here is how you can use the standard tempfile and pytest fixtures to achieve it. We separate the creation of the fixture into a conftest.py file:

```
# content of conftest.py

import pytest
import tempfile
import os

@pytest.fixture()
def cleandir():
    newpath = tempfile.mkdtemp()
    os.chdir(newpath)
```

and declare its use in a test module via a usefixtures marker:

```
# content of test_setenv.py
import os
import pytest

@pytest.mark.usefixtures("cleandir")
class TestDirectoryInit:
    def test_cwd_starts_empty(self):
        assert os.listdir(os.getcwd()) == []
        with open("myfile", "w") as f:
            f.write("hello")

    def test_cwd_again_starts_empty(self):
        assert os.listdir(os.getcwd()) == []
```

Due to the usefixtures marker, the cleandir fixture will be required for the execution of each test method, just as if you specified a "cleandir" function argument to each of them. Let's run it to verify our fixture is activated and the tests pass:

```
$ pytest -q
..
2 passed in 0.12 seconds
```

You can specify multiple fixtures like this:

```
@pytest.mark.usefixtures("cleandir", "anotherfixture")
```

and you may specify fixture usage at the test module level, using a generic feature of the mark mechanism:

```
pytestmark = pytest.mark.usefixtures("cleandir")
```

Note that the assigned variable *must* be called pytestmark, assigning e.g. foomark will not activate the fixtures.

Lastly you can put fixtures required by all tests in your project into an ini-file:

```
# content of pytest.ini
[pytest]
usefixtures = cleandir
```

5.10 Autouse fixtures (xUnit setup on steroids)

Occasionally, you may want to have fixtures get invoked automatically without a *usefixtures* or *funcargs* reference. As a practical example, suppose we have a database fixture which has a begin/rollback/commit architecture and we want to automatically surround each test method by a transaction and a rollback. Here is a dummy self-contained implementation of this idea:

```
# content of test_db_transact.py
import pytest
class DB:
   def init (self):
       self.intransaction = []
   def begin(self, name):
       self.intransaction.append(name)
    def rollback(self):
        self.intransaction.pop()
@pytest.fixture(scope="module")
def db():
   return DB()
class TestClass:
    @pytest.fixture(autouse=True)
    def transact(self, request, db):
        db.begin(request.function.__name__)
        yield
        db.rollback()
    def test_method1(self, db):
        assert db.intransaction == ["test_method1"]
```

```
def test_method2(self, db):
    assert db.intransaction == ["test_method2"]
```

The class-level transact fixture is marked with *autouse=true* which implies that all test methods in the class will use this fixture without a need to state it in the test function signature or with a class-level usefixtures decorator.

If we run it, we get two passing tests:

```
$ pytest -q
..
2 passed in 0.12 seconds
```

Here is how autouse fixtures work in other scopes:

- autouse fixtures obey the scope= keyword-argument: if an autouse fixture has scope='session' it will only be run once, no matter where it is defined. scope='class' means it will be run once per class, etc.
- if an autouse fixture is defined in a test module, all its test functions automatically use it.
- if an autouse fixture is defined in a conftest.py file then all tests in all test modules below its directory will invoke the fixture.
- lastly, and **please use that with care**: if you define an autouse fixture in a plugin, it will be invoked for all tests in all projects where the plugin is installed. This can be useful if a fixture only anyway works in the presence of certain settings e. g. in the ini-file. Such a global fixture should always quickly determine if it should do any work and avoid otherwise expensive imports or computation.

Note that the above transact fixture may very well be a fixture that you want to make available in your project without having it generally active. The canonical way to do that is to put the transact definition into a conftest.py file without using autouse:

```
# content of conftest.py
@pytest.fixture
def transact(self, request, db):
    db.begin()
    yield
    db.rollback()
```

and then e.g. have a TestClass using it by declaring the need:

All test methods in this TestClass will use the transaction fixture while other test classes or functions in the module will not use it unless they also add a transact reference.

5.11 Shifting (visibility of) fixture functions

If during implementing your tests you realize that you want to use a fixture function from multiple test files you can move it to a *conftest.py* file or even separately installable *plugins* without changing test code. The discovery of fixtures functions starts at test classes, then test modules, then conftest.py files and finally builtin and third party plugins.

5.12 Overriding fixtures on various levels

In relatively large test suite, you most likely need to override a global or root fixture with a locally defined one, keeping the test code readable and maintainable.

5.12.1 Override a fixture on a folder (conftest) level

Given the tests file structure is:

```
tests/
   __init__.py
    conftest.py
        # content of tests/conftest.py
        import pytest
        @pytest.fixture
        def username():
           return 'username'
   test_something.py
        # content of tests/test_something.py
        def test_username(username):
           assert username == 'username'
    subfolder/
        __init__.py
        conftest.py
            # content of tests/subfolder/conftest.py
            import pytest
            @pytest.fixture
            def username (username):
                return 'overridden-' + username
        test_something.py
            # content of tests/subfolder/test_something.py
            def test_username(username):
                assert username == 'overridden-username'
```

As you can see, a fixture with the same name can be overridden for certain test folder level. Note that the base or super fixture can be accessed from the overriding fixture easily - used in the example above.

5.12.2 Override a fixture on a test module level

Given the tests file structure is:

```
tests/
   __init__.py

conftest.py
   # content of tests/conftest.py
   @pytest.fixture
   def username():
       return 'username'
```

```
test_something.py
    # content of tests/test_something.py
    import pytest
    @pytest.fixture
    def username(username):
        return 'overridden-' + username
    def test_username(username):
        assert username == 'overridden-username'
test_something_else.py
    # content of tests/test_something_else.py
    import pytest
    @pytest.fixture
    def username (username):
        return 'overridden-else-' + username
    def test_username(username):
        assert username == 'overridden-else-username'
```

In the example above, a fixture with the same name can be overridden for certain test module.

5.12.3 Override a fixture with direct test parametrization

Given the tests file structure is:

```
tests/
   __init__.py
   conftest.py
        # content of tests/conftest.py
       import pytest
       @pytest.fixture
       def username():
           return 'username'
       @pytest.fixture
       def other_username(username):
           return 'other-' + username
   test_something.py
        # content of tests/test_something.py
       import pytest
       @pytest.mark.parametrize('username', ['directly-overridden-username'])
       def test_username(username):
           assert username == 'directly-overridden-username'
       @pytest.mark.parametrize('username', ['directly-overridden-username-other'])
       def test_username_other(other_username):
            assert username == 'other-directly-overridden-username-other'
```

In the example above, a fixture value is overridden by the test parameter value. Note that the value of the fixture can be overridden this way even if the test doesn't use it directly (doesn't mention it in the function prototype).

5.12.4 Override a parametrized fixture with non-parametrized one and vice versa

Given the tests file structure is:

```
tests/
   __init__.py
   conftest.py
        # content of tests/conftest.py
       import pytest
       @pytest.fixture(params=['one', 'two', 'three'])
       def parametrized_username(request):
           return request.param
       @pytest.fixture
       def non_parametrized_username(request):
           return 'username'
   test_something.py
        # content of tests/test_something.py
       import pytest
       @pytest.fixture
       def parametrized_username():
           return 'overridden-username'
       @pytest.fixture(params=['one', 'two', 'three'])
       def non_parametrized_username(request):
            return request.param
       def test_username(parametrized_username):
            assert parametrized_username == 'overridden-username'
       def test_parametrized_username(non_parametrized_username):
            assert non_parametrized_username in ['one', 'two', 'three']
   test_something_else.py
        # content of tests/test_something_else.py
       def test_username(parametrized_username):
            assert parametrized_username in ['one', 'two', 'three']
       def test_username(non_parametrized_username):
            assert non_parametrized_username == 'username'
```

In the example above, a parametrized fixture is overridden with a non-parametrized version, and a non-parametrized fixture is overridden with a parametrized version for certain test module. The same applies for the test folder level obviously.

Monkeypatching/mocking modules and environments

Sometimes tests need to invoke functionality which depends on global settings or which invokes code which cannot be easily tested such as network access. The monkeypatch fixture helps you to safely set/delete an attribute, dictionary item or environment variable or to modify sys.path for importing. See the monkeypatch blog post for some introduction material and a discussion of its motivation.

6.1 Simple example: monkeypatching functions

If you want to pretend that os.expanduser returns a certain directory, you can use the monkeypatch.setattr() method to patch this function before calling into a function which uses it:

```
# content of test_module.py
import os.path
def getssh(): # pseudo application code
    return os.path.join(os.path.expanduser("~admin"), '.ssh')

def test_mytest(monkeypatch):
    def mockreturn(path):
        return '/abc'
    monkeypatch.setattr(os.path, 'expanduser', mockreturn)
    x = getssh()
    assert x == '/abc/.ssh'
```

Here our test function monkeypatches os.path.expanduser and then calls into an function that calls it. After the test function finishes the os.path.expanduser modification will be undone.

6.2 example: preventing "requests" from remote operations

If you want to prevent the "requests" library from performing http requests in all your tests, you can do:

```
# content of conftest.py
import pytest
@pytest.fixture(autouse=True)
def no_requests(monkeypatch):
    monkeypatch.delattr("requests.sessions.Session.request")
```

This autouse fixture will be executed for each test function and it will delete the method request.session.Session.request so that any attempts within tests to create http requests will fail.

6.3 Method reference of the monkeypatch fixture

class MonkeyPatch

Object returned by the monkeypatch fixture keeping a record of setattr/item/env/syspath changes.

setattr (target, name, value=<notset>, raising=True)

Set attribute value on target, memorizing the old value. By default raise AttributeError if the attribute did not exist.

For convenience you can specify a string as target which will be interpreted as a dotted import path, with the last part being the attribute name. Example: monkeypatch.setattr("os.getcwd", lambda x: "/") would set the getcwd function of the os module.

The raising value determines if the setattr should fail if the attribute is not already present (defaults to True which means it will raise).

delattr (target, name=<notset>, raising=True)

Delete attribute name from target, by default raise AttributeError it the attribute did not previously exist.

If no name is specified and target is a string it will be interpreted as a dotted import path with the last part being the attribute name.

If raising is set to False, no exception will be raised if the attribute is missing.

setitem(dic, name, value)

Set dictionary entry name to value.

delitem(dic, name, raising=True)

Delete name from dict. Raise KeyError if it doesn't exist.

If raising is set to False, no exception will be raised if the key is missing.

setenv (name, value, prepend=None)

Set environment variable name to value. If prepend is a character, read the current environment variable value and prepend the value adjoined with the prepend character.

delenv (name, raising=True)

Delete name from the environment. Raise KeyError it does not exist.

If raising is set to False, no exception will be raised if the environment variable is missing.

syspath_prepend(path)

Prepend path to sys.path list of import locations.

chdir (path)

Change the current working directory to the specified path. Path can be a string or a py.path.local object.

undo()

Undo previous changes. This call consumes the undo stack. Calling it a second time has no effect unless you do more monkeypatching after the undo call.

There is generally no need to call *undo()*, since it is called automatically during tear-down.

Note that the same *monkeypatch* fixture is used across a single test function invocation. If *monkeypatch* is used both by the test function itself and one of the test fixtures, calling *undo()* will undo all of the changes made in both functions.

monkeypatch.setattr/delattr/delitem/delenv() all by default raise an Exception if the target does not exist. Pass raising=False if you want to skip this check.

Temporary directories and files

7.1 The 'tmpdir' fixture

You can use the tmpdir fixture which will provide a temporary directory unique to the test invocation, created in the base temporary directory.

tmpdir is a py.path.local object which offers os . path methods and more. Here is an example test usage:

```
# content of test_tmpdir.py
import os
def test_create_file(tmpdir):
    p = tmpdir.mkdir("sub").join("hello.txt")
    p.write("content")
    assert p.read() == "content"
    assert len(tmpdir.listdir()) == 1
    assert 0
```

Running this would result in a passed test except for the last assert 0 line which we use to look at values:

```
$ pytest test_tmpdir.py
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 1 items
test_tmpdir.py F
====== FAILURES ======
   ____ test_create_file ____
tmpdir = local('PYTEST_TMPDIR/test_create_file0')
   def test_create_file(tmpdir):
       p = tmpdir.mkdir("sub").join("hello.txt")
       p.write("content")
       assert p.read() == "content"
       assert len(tmpdir.listdir()) == 1
       assert 0
       assert 0
test_tmpdir.py:7: AssertionError
====== 1 failed in 0.12 seconds ======
```

7.2 The 'tmpdir_factory' fixture

New in version 2.8.

The tmpdir_factory is a session-scoped fixture which can be used to create arbitrary temporary directories from any other fixture or test.

For example, suppose your test suite needs a large image on disk, which is generated procedurally. Instead of computing the same image for each test that uses it into its own tmpdir, you can generate it once per-session to save time:

```
# contents of conftest.py
import pytest

@pytest.fixture(scope='session')
def image_file(tmpdir_factory):
    img = compute_expensive_image()
    fn = tmpdir_factory.mktemp('data').join('img.png')
    img.save(str(fn))
    return fn

# contents of test_image.py
def test_histogram(image_file):
    img = load_image(image_file)
    # compute and test histogram
```

tmpdir_factory instances have the following methods:

```
TempdirFactory.mktemp(basename, numbered=True)
```

Create a subdirectory of the base temporary directory and return it. If numbered, ensure the directory is unique by adding a number prefix greater than any existing one.

```
TempdirFactory.getbasetemp() return base temporary directory.
```

7.3 The default base temporary directory

Temporary directories are by default created as sub-directories of the system temporary directory. The base name will be pytest-NUM where NUM will be incremented with each test run. Moreover, entries older than 3 temporary directories will be removed.

You can override the default temporary directory setting like this:

```
pytest --basetemp=mydir
```

When distributing tests on the local machine, pytest takes care to configure a basetemp directory for the sub processes such that all temporary data lands below a single per-test run basetemp directory.

Capturing of the stdout/stderr output

8.1 Default stdout/stderr/stdin capturing behaviour

During test execution any output sent to stdout and stderr is captured. If a test or a setup method fails its according captured output will usually be shown along with the failure traceback.

In addition, stdin is set to a "null" object which will fail on attempts to read from it because it is rarely desired to wait for interactive input when running automated tests.

By default capturing is done by intercepting writes to low level file descriptors. This allows to capture output from simple print statements as well as output from a subprocess started by a test.

8.2 Setting capturing methods or disabling capturing

There are two ways in which pytest can perform capturing:

- file descriptor (FD) level capturing (default): All writes going to the operating system file descriptors 1 and 2 will be captured.
- sys level capturing: Only writes to Python files sys.stdout and sys.stderr will be captured. No capturing of writes to filedescriptors is performed.

You can influence output capturing mechanisms from the command line:

```
pytest -s  # disable all capturing
pytest --capture=sys # replace sys.stdout/stderr with in-mem files
pytest --capture=fd # also point filedescriptors 1 and 2 to temp file
```

8.3 Using print statements for debugging

One primary benefit of the default capturing of stdout/stderr output is that you can use print statements for debugging:

```
# content of test_module.py

def setup_function(function):
    print ("setting up %s" % function)

def test_func1():
    assert True
```

```
def test_func2():
    assert False
```

and running this module will show you precisely the output of the failing function and hide the other one:

```
$ pytest
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items
test_module.py .F
====== FAILURES ======
     _ test_func2 ___
   def test_func2():
      assert False
E
       assert False
test_module.py:9: AssertionError
---- Captured stdout setup ---
setting up <function test_func2 at 0xdeadbeef>
====== 1 failed, 1 passed in 0.12 seconds =======
```

8.4 Accessing captured output from a test function

The capsys and capfd fixtures allow to access stdout/stderr output created during test execution. Here is an example test function that performs some output related checks:

```
def test_myoutput(capsys): # or use "capfd" for fd-level
    print ("hello")
    sys.stderr.write("world\n")
    out, err = capsys.readouterr()
    assert out == "hello\n"
    assert err == "world\n"
    print ("next")
    out, err = capsys.readouterr()
    assert out == "next\n"
```

The readouterr() call snapshots the output so far - and capturing will be continued. After the test function finishes the original streams will be restored. Using capsys this way frees your test from having to care about setting/resetting output streams and also interacts well with pytest's own per-test capturing.

If you want to capture on filedescriptor level you can use the capfd function argument which offers the exact same interface but allows to also capture output from libraries or subprocesses that directly write to operating system level output streams (FD1 and FD2).

New in version 3.0.

To temporarily disable capture within a test, both capsys and capfd have a disabled() method that can be used as a context manager, disabling capture inside the with block:

```
def test_disabling_capturing(capsys):
    print('this output is captured')
    with capsys.disabled():
```

print('output not captured, going directly to sys.stdout')
print('this output is also captured')

Asserting Warnings

9.1 Asserting warnings with the warns function

New in version 2.8.

You can check that code raises a particular warning using pytest.warns, which works in a similar manner to raises:

```
import warnings
import pytest

def test_warning():
    with pytest.warns(UserWarning):
        warnings.warn("my warning", UserWarning)
```

The test will fail if the warning in question is not raised.

You can also call pytest.warns on a function or code string:

```
pytest.warns(expected_warning, func, *args, **kwargs)
pytest.warns(expected_warning, "func(*args, **kwargs)")
```

The function also returns a list of all raised warnings (as warnings.WarningMessage objects), which you can query for additional information:

```
with pytest.warns(RuntimeWarning) as record:
    warnings.warn("another warning", RuntimeWarning)

# check that only one warning was raised
assert len(record) == 1
# check that the message matches
assert record[0].message.args[0] == "another warning"
```

Alternatively, you can examine raised warnings in detail using the *recwarn* fixture (see below).

Note: DeprecationWarning and PendingDeprecationWarning are treated differently; see *Ensuring a function triggers a deprecation warning*.

9.2 Recording warnings

You can record raised warnings either using pytest.warns or with the recwarn fixture.

To record with pytest.warns without asserting anything about the warnings, pass None as the expected warning type:

```
with pytest.warns(None) as record:
    warnings.warn("user", UserWarning)
    warnings.warn("runtime", RuntimeWarning)

assert len(record) == 2
assert str(record[0].message) == "user"
assert str(record[1].message) == "runtime"
```

The recwarn fixture will record warnings for the whole function:

```
import warnings

def test_hello(recwarn):
    warnings.warn("hello", UserWarning)
    assert len(recwarn) == 1
    w = recwarn.pop(UserWarning)
    assert issubclass(w.category, UserWarning)
    assert str(w.message) == "hello"
    assert w.filename
    assert w.lineno
```

Both recwarn and pytest.warns return the same interface for recorded warnings: a WarningsRecorder instance. To view the recorded warnings, you can iterate over this instance, call len on it to get the number of recorded warnings, or index into it to get a particular recorded warning. It also provides these methods:

class WarningsRecorder

A context manager to record raised warnings.

Adapted from warnings.catch_warnings.

list

The list of recorded warnings.

```
pop (cls=<type 'exceptions.Warning'>)
```

Pop the first recorded warning, raise exception if not exists.

clear()

Clear the list of recorded warnings.

Each recorded warning has the attributes message, category, filename, lineno, file, and line. The category is the class of the warning. The message is the warning itself; calling str (message) will return the actual message of the warning.

Note: DeprecationWarning and PendingDeprecationWarning are treated differently; see *Ensuring a function triggers a deprecation warning*.

9.3 Ensuring a function triggers a deprecation warning

You can also call a global helper for checking that a certain function call triggers a DeprecationWarning or PendingDeprecationWarning:

```
import pytest

def test_global():
    pytest.deprecated_call(myfunction, 17)
```

By default, DeprecationWarning and PendingDeprecationWarning will not be caught when using pytest.warns or recwarn because default Python warnings filters hide them. If you wish to record them in your own code, use the command warnings.simplefilter('always'):

```
import warnings
import pytest

def test_deprecation(recwarn):
    warnings.simplefilter('always')
    warnings.warn("deprecated", DeprecationWarning)
    assert len(recwarn) == 1
    assert recwarn.pop(DeprecationWarning)
```

You can also use it as a contextmanager:

```
def test_global():
    with pytest.deprecated_call():
        myobject.deprecated_method()
```

Doctest integration for modules and test files

By default all files matching the test*.txt pattern will be run through the python standard doctest module. You can change the pattern by issuing:

```
pytest --doctest-glob='*.rst'
```

on the command line. Since version 2.9, --doctest-glob can be given multiple times in the command-line.

You can also trigger running of doctests from docstrings in all python modules (including regular python test modules):

```
pytest --doctest-modules
```

You can make these changes permanent in your project by putting them into a pytest.ini file like this:

```
# content of pytest.ini
[pytest]
addopts = --doctest-modules
```

If you then have a text file like this:

```
# content of example.rst
hello this is a doctest
>>> x = 3
>>> x
3
```

and another like this:

```
# content of mymodule.py
def something():
    """ a doctest in a docstring
    >>> something()
    42
    """
    return 42
```

then you can just invoke pytest without command line options:

```
$ pytest
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile: pytest.ini
collected 1 items

mymodule.py .
```

```
====== 1 passed in 0.12 seconds ======
```

It is possible to use fixtures using the getfixture helper:

```
# content of example.rst
>>> tmp = getfixture('tmpdir')
>>> ...
>>>
```

Also, Using fixtures from classes, modules or projects and Autouse fixtures (xUnit setup on steroids) fixtures are supported when executing text doctest files.

The standard doctest module provides some setting flags to configure the strictness of doctest tests. In pytest You can enable those flags those flags using the configuration file. To make pytest ignore trailing whitespaces and ignore lengthy exception stack traces you can just write:

```
[pytest]
doctest_optionflags= NORMALIZE_WHITESPACE IGNORE_EXCEPTION_DETAIL
```

pytest also introduces new options to allow doctests to run in Python 2 and Python 3 unchanged:

- ALLOW_UNICODE: when enabled, the u prefix is stripped from unicode strings in expected doctest output.
- ALLOW_BYTES: when enabled, the b prefix is stripped from byte strings in expected doctest output.

As with any other option flag, these flags can be enabled in pytest.ini using the doctest_optionflags ini option:

```
[pytest]
doctest_optionflags = ALLOW_UNICODE ALLOW_BYTES
```

Alternatively, it can be enabled by an inline comment in the doc test itself:

```
# content of example.rst
>>> get_unicode_greeting() # doctest: +ALLOW_UNICODE
'Hello'
```

10.1 The 'doctest_namespace' fixture

New in version 3.0.

The doctest_namespace fixture can be used to inject items into the namespace in which your doctests run. It is intended to be used within your own fixtures to provide the tests that use them with context.

doctest_namespace is a standard dict object into which you place the objects you want to appear in the doctest namespace:

```
# content of conftest.py
import numpy
@pytest.fixture(autouse=True)
def add_np(doctest_namespace):
    doctest_namespace['np'] = numpy
```

which can then be used in your doctests directly:

```
# content of numpy.py
def arange():
    """
    >>> a = np.arange(10)
```

```
>>> len(a)
10
"""
pass
```

10.2 Output format

New in version 3.0.

You can change the diff output format on failure for your doctests by using one of standard doctest modules format in options (see doctest.REPORT_UDIFF, doctest.REPORT_CDIFF, doctest.REPORT_ONLY_FIRST_FAILURE):

```
pytest --doctest-modules --doctest-report none
pytest --doctest-modules --doctest-report udiff
pytest --doctest-modules --doctest-report cdiff
pytest --doctest-modules --doctest-report ndiff
pytest --doctest-modules --doctest-report only_first_failure
```

10.2. Output format 57

Marking test functions with attributes

By using the pytest.mark helper you can easily set metadata on your test functions. There are some builtin markers, for example:

- skipif skip a test function if a certain condition is met
- xfail produce an "expected failure" outcome if a certain condition is met
- parametrize to perform multiple calls to the same test function.

It's easy to create custom markers or to apply markers to whole test classes or modules. See *Working with custom markers* for examples which also serve as documentation.

Note: Marks can only be applied to tests, having no effect on *fixtures*.

11.1 API reference for mark related objects

class MarkGenerator

Factory for MarkDecorator objects - exposed as a pytest.mark singleton instance. Example:

```
import pytest
@pytest.mark.slowtest
def test_function():
    pass
```

will set a 'slowtest' MarkInfo object on the test_function object.

class MarkDecorator (name, args=None, kwargs=None)

A decorator for test functions and test classes. When applied it will create <code>MarkInfo</code> objects which may be retrieved by hooks as item keywords. MarkDecorator instances are often created like this:

```
mark1 = pytest.mark.NAME  # simple MarkDecorator
mark2 = pytest.mark.NAME(name1=value) # parametrized MarkDecorator
```

and can then be applied as decorators to test functions:

```
@mark2
def test_function():
    pass
```

When a MarkDecorator instance is called it does the following:

- 1. If called with a single class as its only positional argument and no additional keyword arguments, it attaches itself to the class so it gets applied automatically to all test cases found in that class.
- If called with a single function as its only positional argument and no additional keyword arguments, it attaches a MarkInfo object to the function, containing all the arguments already stored internally in the MarkDecorator.
- When called in any other case, it performs a 'fake construction' call, i.e. it returns a new MarkDecorator instance with the original MarkDecorator's content updated with the arguments passed to this call.

Note: The rules above prevent MarkDecorator objects from storing only a single function or class reference as their positional argument with no additional keyword or positional arguments.

class MarkInfo (name, args, kwargs)

Marking object created by MarkDecorator instances.

name = None

name of attribute

args = None

positional argument list, empty if none specified

kwargs = None

keyword argument dictionary, empty if nothing specified

add (args, kwargs)

add a MarkInfo with the given args and kwargs.

Skip and xfail: dealing with tests that can not succeed

If you have test functions that cannot be run on certain platforms or that you expect to fail you can mark them accordingly or you may call helper functions during execution of setup or test functions.

A *skip* means that you expect your test to pass unless the environment (e.g. wrong Python interpreter, missing dependency) prevents it to run. And *xfail* means that your test can run but you expect it to fail because there is an implementation problem.

pytest counts and lists *skip* and *xfail* tests separately. Detailed information about skipped/xfailed tests is not shown by default to avoid cluttering the output. You can use the -r option to see details corresponding to the "short" letters shown in the test progress:

```
pytest -rxs # show extra info on skips and xfails
```

(See *How to change command line options defaults*)

12.1 Marking a test function to be skipped

New in version 2.9.

The simplest way to skip a test function is to mark it with the skip decorator which may be passed an optional reason:

```
@pytest.mark.skip(reason="no way of currently testing this")
def test_the_unknown():
    ...
```

12.1.1 skipif

New in version 2.0,: 2.4

If you wish to skip something conditionally then you can use skipif instead. Here is an example of marking a test function to be skipped when run on a Python3.3 interpreter:

During test function setup the condition ("sys.version_info >= (3,3)") is checked. If it evaluates to True, the test function will be skipped with the specified reason. Note that pytest enforces specifying a reason in order to report meaningful "skip reasons" (e.g. when using -rs). If the condition is a string, it will be evaluated as python expression.

You can share skipif markers between modules. Consider this test module:

You can import it from another test module:

```
# test_myothermodule.py
from test_mymodule import minversion

@minversion
def test_anotherfunction():
    ...
```

For larger test suites it's usually a good idea to have one file where you define the markers which you then consistently apply throughout your test suite.

Alternatively, the pre pytest-2.4 way to specify *condition strings* instead of booleans will remain fully supported in future versions of pytest. It couldn't be easily used for importing markers between test modules so it's no longer advertised as the primary method.

12.2 Skip all test functions of a class or module

You can use the skipif decorator (and any other marker) on classes:

If the condition is true, this marker will produce a skip result for each of the test methods.

If you want to skip all test functions of a module, you must use the pytestmark name on the global level:

```
# test_module.py
pytestmark = pytest.mark.skipif(...)
```

If multiple "skipif" decorators are applied to a test function, it will be skipped if any of the skip conditions is true.

12.3 Mark a test function as expected to fail

You can use the xfail marker to indicate that you expect a test to fail:

```
@pytest.mark.xfail
def test_function():
    ...
```

This test will be run but no traceback will be reported when it fails. Instead terminal reporting will list it in the "expected to fail" (XFAIL) or "unexpectedly passing" (XPASS) sections.

12.3.1 strict parameter

New in version 2.9.

Both XFAIL and XPASS don't fail the test suite, unless the strict keyword-only parameter is passed as True:

```
@pytest.mark.xfail(strict=True)
def test_function():
    ...
```

This will make XPASS ("unexpectedly passing") results from this test to fail the test suite.

You can change the default value of the strict parameter using the xfail_strict ini option:

```
[pytest]
xfail_strict=true
```

12.3.2 reason parameter

As with *skipif* you can also mark your expectation of a failure on a particular platform:

12.3.3 raises parameter

If you want to be more specific as to why the test is failing, you can specify a single exception, or a list of exceptions, in the raises argument.

```
@pytest.mark.xfail(raises=RuntimeError)
def test_function():
    ...
```

Then the test will be reported as a regular failure if it fails with an exception not mentioned in raises.

12.3.4 run parameter

If a test should be marked as xfail and reported as such but should not be even executed, use the run parameter as False:

```
@pytest.mark.xfail(run=False)
def test_function():
    ...
```

This is specially useful for marking crashing tests for later inspection.

12.3.5 Ignoring xfail marks

By specifying on the commandline:

```
pytest --runxfail
```

you can force the running and reporting of an xfail marked test as if it weren't marked at all.

12.3.6 Examples

Here is a simple test file with the several usages:

```
import pytest
xfail = pytest.mark.xfail
@xfail
def test_hello():
   assert 0
@xfail(run=False)
def test_hello2():
   assert 0
@xfail("hasattr(os, 'sep')")
def test_hello3():
   assert 0
@xfail(reason="bug 110")
def test_hello4():
    assert 0
@xfail('pytest.__version__[0] != "17"')
def test_hello5():
    assert 0
def test hello6():
   pytest.xfail("reason")
@xfail (raises=IndexError)
def test_hello7():
    x = []
    x[1] = 1
```

Running it with the report-on-xfail option gives this output:

```
example $ pytest -rx xfail_demo.py
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR/example, inifile:
collected 7 items

xfail_demo.py xxxxxxx
====== short test summary info ======
XFAIL xfail_demo.py::test_hello
XFAIL xfail_demo.py::test_hello2
    reason: [NOTRUN]
XFAIL xfail_demo.py::test_hello3
    condition: hasattr(os, 'sep')
```

```
XFAIL xfail_demo.py::test_hello4
  bug 110
XFAIL xfail_demo.py::test_hello5
  condition: pytest.__version__[0] != "17"
XFAIL xfail_demo.py::test_hello6
  reason: reason
XFAIL xfail_demo.py::test_hello7
======= 7 xfailed in 0.12 seconds ========
```

12.3.7 xfail signature summary

Here's the signature of the xfail marker, using Python 3 keyword-only arguments syntax:

```
def xfail(condition=None, *, reason=None, raises=None, run=True, strict=False):
```

12.4 Skip/xfail with parametrize

It is possible to apply markers like skip and xfail to individual test instances when using parametrize:

12.5 Imperative xfail from within a test or setup function

If you cannot declare xfail- of skipif conditions at import time you can also imperatively produce an according outcome imperatively, in test or setup code:

```
def test_function():
    if not valid_config():
        pytest.xfail("failing configuration (but should work)")
        # or
        pytest.skip("unsupported configuration")
```

12.6 Skipping on a missing import dependency

You can use the following import helper at module level or within a test or test setup function:

```
docutils = pytest.importorskip("docutils")
```

If docutils cannot be imported here, this will lead to a skip outcome of the test. You can also skip based on the version number of a library:

```
docutils = pytest.importorskip("docutils", minversion="0.3")
```

The version will be read from the specified module's __version__ attribute.

12.7 specifying conditions as strings versus booleans

Prior to pytest-2.4 the only way to specify skipif/xfail conditions was to use strings:

```
import sys
@pytest.mark.skipif("sys.version_info >= (3,3)")
def test_function():
    ...
```

During test function setup the skipif condition is evaluated by calling eval('sys.version_info >= (3,0)', namespace). The namespace contains all the module globals, and os and sys as a minimum.

Since pytest-2.4 *condition booleans* are considered preferable because markers can then be freely imported between test modules. With strings you need to import not only the marker but all variables everything used by the marker, which violates encapsulation.

The reason for specifying the condition as a string was that pytest can report a summary of skip conditions based purely on the condition string. With conditions as booleans you are required to specify a reason string.

Note that string conditions will remain fully supported and you are free to use them if you have no need for cross-importing markers.

The evaluation of a condition string in pytest.mark.skipif(conditionstring) or pytest.mark.xfail(conditionstring) takes place in a namespace dictionary which is constructed as follows:

- the namespace is initialized by putting the sys and os modules and the pytest config object into it.
- updated with the module globals of the test function for which the expression is applied.

The pytest config object allows you to skip based on a test configuration value which you might have added:

```
@pytest.mark.skipif("not config.getvalue('db')")
def test_function(...):
    ...
```

The equivalent with "boolean conditions" is:

Note: You cannot use pytest.config.getvalue() in code imported before pytest's argument parsing takes place. For example, conftest.py files are imported before command line parsing and thus config.getvalue() will not execute correctly.

Parametrizing fixtures and test functions

pytest supports test parametrization in several well-integrated ways:

- pytest.fixture() allows to define parametrization at the level of fixture functions.
- @pytest.mark.parametrize allows to define parametrization at the function or class level, provides multiple argument/fixture sets for a particular test function or class.
- pytest_generate_tests enables implementing your own custom dynamic parametrization scheme or extensions.

13.1 @pytest.mark.parametrize: parametrizing test functions

New in version 2.2.

Changed in version 2.4: Several improvements.

The builtin pytest.mark.parametrize decorator enables parametrization of arguments for a test function. Here is a typical example of a test function that implements checking that a certain input leads to an expected output:

Here, the @parametrize decorator defines three different (test_input,expected) tuples so that the test_eval function will run three times using them in turn:

```
$ pytest
====== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 3 items

test_expectation.py ..F
====== FAILURES =======
_____ test_eval[6*9-42] _____
test_input = '6*9', expected = 42
```

As designed in this example, only one pair of input/output values fails the simple test function. And as usual with test function arguments, you can see the input and output values in the traceback.

Note that you could also use the parametrize marker on a class or a module (see *Marking test functions with attributes*) which would invoke several functions with the argument sets.

It is also possible to mark individual test instances within parametrize, for example with the builtin mark.xfail:

Let's run this:

```
$ pytest
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 3 items

test_expectation.py ..x
====== 2 passed, 1 xfailed in 0.12 seconds =======
```

The one parameter set which caused a failure previously now shows up as an "xfailed (expected to fail)" test.

To get all combinations of multiple parametrized arguments you can stack parametrize decorators:

```
import pytest
@pytest.mark.parametrize("x", [0, 1])
@pytest.mark.parametrize("y", [2, 3])
def test_foo(x, y):
    pass
```

This will run the test with the arguments set to x=0/y=2, x=0/y=3, x=1/y=2 and x=1/y=3.

Note: In versions prior to 2.4 one needed to specify the argument names as a tuple. This remains valid but the simpler "name1, name2, ..." comma-separated-string syntax is now advertised first because it's easier to write and produces less line noise.

13.2 Basic pytest_generate_tests example

Sometimes you may want to implement your own parametrization scheme or implement some dynamism for determining the parameters or scope of a fixture. For this, you can use the pytest_generate_tests hook which is called when collecting a test function. Through the passed in metafunc object you can inspect the requesting test context and, most importantly, you can call metafunc.parametrize() to cause parametrization.

For example, let's say we want to run a test taking string inputs which we want to set via a new pytest command line option. Let's first write a simple test accepting a stringinput fixture function argument:

```
# content of test_strings.py

def test_valid_string(stringinput):
    assert stringinput.isalpha()
```

Now we add a conftest.py file containing the addition of a command line option and the parametrization of our test function:

If we now pass two stringinput values, our test will run twice:

```
$ pytest -q --stringinput="hello" --stringinput="world" test_strings.py
..
2 passed in 0.12 seconds
```

Let's also run with a stringinput that will lead to a failing test:

As expected our test function fails.

If you don't specify a stringinput it will be skipped because metafunc.parametrize() will be called with an empty parameter list:

```
$ pytest -q -rs test_strings.py
s
====== short test summary info ======
SKIP [1] test_strings.py:1: got empty parameter set ['stringinput'], function test_valid_string at $1
1 skipped in 0.12 seconds
```

For further examples, you might want to look at more parametrization examples.

13.3 The metafunc object

class Metafunc (function, fixture info, config, cls=None, module=None)

Metafunc objects are passed to the pytest_generate_tests hook. They help to inspect a test function and to generate tests according to test configuration or values specified in the class or module where a test function is defined.

config = None

access to the _pytest.config.Config object for the test session

module = None

the module object where the test function is defined in.

function = None

underlying python test function

fixturenames = None

set of fixture names required by the test function

cls = None

class object where the test function is defined in or None.

```
parametrize (argnames, argvalues, indirect=False, ids=None, scope=None)
```

Add new invocations to the underlying test function using the list of argvalues for the given argnames. Parametrization is performed during the collection phase. If you need to setup expensive resources see about setting indirect to do it rather at test setup time.

Parameters

- argnames a comma-separated string denoting one or more argument names, or a list/tuple of argument strings.
- **argvalues** The list of argvalues determines how often a test is invoked with different argument values. If only one argname was specified argvalues is a list of values. If N argnames were specified, argvalues must be a list of N-tuples, where each tuple-element specifies a value for its respective argname.
- indirect The list of argnames or boolean. A list of arguments' names (subset of argnames). If True the list contains all names from the argnames. Each argvalue corresponding to an argname in this list will be passed as request.param to its respective argname fixture function so that it can perform more expensive setups during the setup phase of a test rather than at collection time.
- ids list of string ids, or a callable. If strings, each is corresponding to the argvalues so that they are part of the test id. If None is given as id of specific test, the automatically generated id for that argument will be used. If callable, it should take one argument (a single argvalue) and return a string or return None. If None, the automatically generated id for that argument will be used. If no ids are provided they will be generated automatically from the argvalues.

• **scope** – if specified it denotes the scope of the parameters. The scope is used for grouping tests by parameter instances. It will also override any fixture-function defined scope, allowing to set a dynamic scope using test context or configuration.

addcall (funcargs=None, id=<object object>, param=<object object>)

(deprecated, use parametrize) Add a new call to the underlying test function during the collection phase of a test run. Note that request.addcall() is called during the test collection phase prior and independently to actual test execution. You should only use addcall() if you need to specify multiple arguments of a test function.

Parameters

- **funcargs** argument keyword dictionary used when invoking the test function.
- id used for reporting and identification purposes. If you don't supply an *id* an automatic unique id will be generated.
- param a parameter which will be exposed to a later fixture function invocation through the request.param attribute.

Cache: working with cross-testrun state

New in version 2.8.

Warning: The functionality of this core plugin was previously distributed as a third party plugin named pytest-cache. The core plugin is compatible regarding command line options and API usage except that you can only store/receive data between test runs that is json-serializable.

14.1 Usage

The plugin provides two command line options to rerun failures from the last pytest invocation:

- --lf, --last-failed to only re-run the failures.
- --ff, --failed-first to run the failures first and then the rest of the tests.

For cleanup (usually not needed), a --cache-clear option allows to remove all cross-session cache contents ahead of a test run.

Other plugins may access the *config.cache* object to set/get **json encodable** values between pytest invocations.

Note: This plugin is enabled by default, but can be disabled if needed: see *Deactivating / unregistering a plugin by name* (the internal name for this plugin is cacheprovider).

14.2 Rerunning only failures or failures first

First, let's create 50 test invocation of which only 2 fail:

```
# content of test_50.py
import pytest

@pytest.mark.parametrize("i", range(50))
def test_num(i):
    if i in (17, 25):
        pytest.fail("bad luck")
```

If you run this for the first time you will see two failures:

```
$ pytest -q
====== FAILURES ======
 ____ test_num[17] ___
i = 17
   @pytest.mark.parametrize("i", range(50))
   def test_num(i):
      if i in (17, 25):
         pytest.fail("bad luck")
Ε
         Failed: bad luck
test_50.py:6: Failed
_____ test_num[25] _____
i = 25
   @pytest.mark.parametrize("i", range(50))
   def test_num(i):
      if i in (17, 25):
         pytest.fail("bad luck")
Ε
         Failed: bad luck
test_50.py:6: Failed
2 failed, 48 passed in 0.12 seconds
```

If you then run it with --1f:

```
$ pytest --1f
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
run-last-failure: rerun last 2 failures
rootdir: $REGENDOC_TMPDIR, inifile:
collected 50 items
test_50.py FF
====== FAILURES ======
 _____ test_num[17] ____
i = 17
   @pytest.mark.parametrize("i", range(50))
   def test_num(i):
       if i in (17, 25):
          pytest.fail("bad luck")
Ε
          Failed: bad luck
test_50.py:6: Failed
 _____ test_num[25] _____
i = 25
    @pytest.mark.parametrize("i", range(50))
   def test_num(i):
       if i in (17, 25):
          pytest.fail("bad luck")
```

```
E Failed: bad luck

test_50.py:6: Failed
====== 48 tests deselected =======
==== 2 failed, 48 deselected in 0.12 seconds =======
```

You have run only the two failing test from the last run, while 48 tests have not been run ("deselected").

Now, if you run with the --ff option, all tests will be run but the first previous failures will be executed first (as can be seen from the series of FF and dots):

```
$ pytest --ff
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
run-last-failure: rerun last 2 failures first
rootdir: $REGENDOC_TMPDIR, inifile:
collected 50 items
test_50.py FF.....
====== FAILURES ======
     __ test_num[17] __
i = 17
   @pytest.mark.parametrize("i", range(50))
   def test_num(i):
       if i in (17, 25):
          pytest.fail("bad luck")
Ε
          Failed: bad luck
test_50.py:6: Failed
  _____ test_num[25] __
i = 25
   @pytest.mark.parametrize("i", range(50))
   def test_num(i):
       if i in (17, 25):
          pytest.fail("bad luck")
          Failed: bad luck
test_50.py:6: Failed
====== 2 failed, 48 passed in 0.12 seconds =======
```

14.3 The new config.cache object

Plugins or conftest.py support code can get a cached value using the pytest config object. Here is a basic example plugin which implements a *pytest fixtures: explicit, modular, scalable* which re-uses previously created state across pytest invocations:

```
# content of test_caching.py
import pytest
import time
@pytest.fixture
```

```
def mydata(request):
    val = request.config.cache.get("example/value", None)
    if val is None:
        time.sleep(9*0.6) # expensive computation :)
        val = 42
        request.config.cache.set("example/value", val)
    return val

def test_function(mydata):
    assert mydata == 23
```

If you run this command once, it will take a while because of the sleep:

```
$ pytest -q
F
====== FAILURES ======
______ test_function _____

mydata = 42

   def test_function(mydata):
>        assert mydata == 23
E        assert 42 == 23

test_caching.py:14: AssertionError
1 failed in 0.12 seconds
```

If you run it a second time the value will be retrieved from the cache and this will be quick:

```
$ pytest -q
F
====== FAILURES ======
______ test_function _____

mydata = 42

   def test_function(mydata):
>   assert mydata == 23
E   assert 42 == 23

test_caching.py:14: AssertionError
1 failed in 0.12 seconds
```

See the *cache-api* for more details.

14.4 Inspecting Cache content

You can always peek at the content of the cache using the --cache-show command line option:

```
cache/lastfailed contains:
    {'test_caching.py::test_function': True}
====== no tests ran in 0.12 seconds ========
```

14.5 Clearing Cache content

You can instruct pytest to clear all cache files and values by adding the --cache-clear option like this:

```
pytest --cache-clear
```

This is recommended for invocations from Continous Integration servers where isolation and correctness is more important than speed.

14.6 config.cache API

The config.cache object allows other plugins, including conftest.py files, to safely and flexibly store and retrieve values across test runs because the config object is available in many places.

Under the hood, the cache plugin uses the simple dumps/loads API of the json stdlib module

Cache.get (key, default)

return cached value for the given key. If no value was yet cached or the value cannot be read, the specified default is returned.

Parameters

- **key** must be a / separated value. Usually the first name is the name of your plugin or your application.
- **default** must be provided in case of a cache-miss or invalid cache values.

Cache.set (key, value)

save value for the given key.

Parameters

- **key** must be a / separated value. Usually the first name is the name of your plugin or your application.
- **value** must be of any combination of basic python types, including nested types like e. g. lists of dictionaries.

Cache.makedir(name)

return a directory path object with the given name. If the directory does not yet exist, it will be created. You can use it to manage files likes e. g. store/retrieve database dumps across test sessions.

Parameters name – must be a string not containing a / separator. Make sure the name contains your plugin or application identifiers to prevent clashes with other cache users.

Support for unittest.TestCase / Integration of fixtures

pytest has support for running Python unittest.py style tests. It's meant for leveraging existing unittest-style projects to use pytest features. Concretely, pytest will automatically collect unittest.TestCase subclasses and their test methods in test files. It will invoke typical setup/teardown methods and generally try to make test suites written to run on unittest, to also run using pytest. We assume here that you are familiar with writing unittest.TestCase style tests and rather focus on integration aspects.

15.1 Usage

After *Installation* type:

pytest

and you should be able to run your unittest-style tests if they are contained in test_* modules. If that works for you then you can make use of most pytest features, for example --pdb debugging in failures, using *plain assert-statements*, *more informative tracebacks*, stdout-capturing or distributing tests to multiple CPUs via the -nNUM option if you installed the pytest-xdist plugin. Please refer to the general pytest documentation for many more examples.

Note: Running tests from unittest.TestCase subclasses with --pdb will disable tearDown and cleanup methods for the case that an Exception occurs. This allows proper post mortem debugging for all applications which have significant logic in their tearDown machinery. However, supporting this feature has the following side effect: If people overwrite unittest.TestCase __call__ or run, they need to to overwrite debug in the same way (this is also true for standard unittest).

15.2 Mixing pytest fixtures into unittest. Test Case style tests

Running your unittest with pytest allows you to use its *fixture mechanism* with unittest. TestCase style tests. Assuming you have at least skimmed the pytest fixture features, let's jump-start into an example that integrates a pytest db_class fixture, setting up a class-cached database object, and then reference it from a unittest-style test:

```
# content of conftest.py

# we define a fixture function below and it will be "used" by
# referencing its name from tests
import pytest
```

```
@pytest.fixture(scope="class")
def db_class(request):
    class DummyDB:
        pass
    # set a class attribute on the invoking test context
    request.cls.db = DummyDB()
```

This defines a fixture function db_class which - if used - is called once for each test class and which sets the class-level db attribute to a DummyDB instance. The fixture function achieves this by receiving a special request object which gives access to the requesting test context such as the cls attribute, denoting the class from which the fixture is used. This architecture de-couples fixture writing from actual test code and allows re-use of the fixture by a minimal reference, the fixture name. So let's write an actual unittest. TestCase class using our fixture definition:

```
# content of test_unittest_db.py

import unittest
import pytest

@pytest.mark.usefixtures("db_class")
class MyTest(unittest.TestCase):
    def test_method1(self):
        assert hasattr(self, "db")
        assert 0, self.db # fail for demo purposes

def test_method2(self):
    assert 0, self.db # fail for demo purposes
```

The @pytest.mark.usefixtures("db_class") class-decorator makes sure that the pytest fixture function db_class is called once per class. Due to the deliberately failing assert statements, we can take a look at the self.db values in the traceback:

```
$ pytest test_unittest_db.py
====== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items
test_unittest_db.py FF
====== FAILURES ======
      _ MyTest.test_method1 _
self = <test_unittest_db.MyTest testMethod=test_method1>
    def test_method1(self):
        assert hasattr(self, "db")
        assert 0, self.db  # fail for demo purposes
\mathbf{E}
       AssertionError: <conftest.db_class.<locals>.DummyDB object at 0xdeadbeef>
E
        assert 0
test_unittest_db.py:9: AssertionError
    ____ MyTest.test_method2 _
self = <test_unittest_db.MyTest testMethod=test_method2>
    def test_method2(self):
        assert 0, self.db
                            # fail for demo purposes
        AssertionError: <conftest.db_class.<locals>.DummyDB object at 0xdeadbeef>
```

```
E assert 0

test_unittest_db.py:12: AssertionError
====== 2 failed in 0.12 seconds ========
```

This default pytest traceback shows that the two test methods share the same self.db instance which was our intention when writing the class-scoped fixture function above.

15.3 autouse fixtures and accessing other fixtures

Although it's usually better to explicitly declare use of fixtures you need for a given test, you may sometimes want to have fixtures that are automatically used in a given context. After all, the traditional style of unittest-setup mandates the use of this implicit fixture writing and chances are, you are used to it or like it.

You can flag fixture functions with <code>@pytest.fixture</code> (<code>autouse=True</code>) and define the fixture function in the context where you want it used. Let's look at an <code>initdir</code> fixture which makes all test methods of a <code>TestCase</code> class execute in a temporary directory with a pre-initialized <code>samplefile.ini</code>. Our <code>initdir</code> fixture itself uses the pytest builtin <code>tmpdir</code> fixture to delegate the creation of a per-test temporary directory:

```
# content of test_unittest_cleandir.py
import pytest
import unittest

class MyTest (unittest.TestCase):
    @pytest.fixture(autouse=True)
    def initdir(self, tmpdir):
        tmpdir.chdir() # change to pytest-provided temporary directory
        tmpdir.join("samplefile.ini").write("# testdata")

def test_method(self):
    s = open("samplefile.ini").read()
    assert "testdata" in s
```

Due to the autouse flag the initdir fixture function will be used for all methods of the class where it is defined. This is a shortcut for using a @pytest.mark.usefixtures("initdir") marker on the class like in the previous example.

Running this test module ...:

```
$ pytest -q test_unittest_cleandir.py
.
1 passed in 0.12 seconds
```

... gives us one passed test because the initdir fixture function was executed ahead of the test method.

Note: While pytest supports receiving fixtures via *test function arguments* for non-unittest test methods, unittest.TestCase methods cannot directly receive fixture function arguments as implementing that is likely to inflict on the ability to run general unittest.TestCase test suites. Maybe optional support would be possible, though. If unittest finally grows a plugin system that should help as well. In the meanwhile, the above usefixtures and autouse examples should help to mix in pytest fixtures into unittest suites. And of course you can also start to selectively leave away the unittest.TestCase subclassing, use plain asserts and get the unlimited pytest feature set.

15.4 Converting from unittest to pytest

If you want to convert your unittest testcases to pytest, there are some helpers like unittest2pytest, which uses lib2to3 and introspection for the transformation.

Running tests written for nose

pytest has basic support for running tests written for nose.

16.1 Usage

After Installation type:

```
python setup.py develop # make sure tests can import our package
pytest # instead of 'nosetests'
```

and you should be able to run your nose style tests and make use of pytest's capabilities.

16.2 Supported nose Idioms

- setup and teardown at module/class/method level
- SkipTest exceptions and markers
- · setup/teardown decorators
- yield-based tests and their setup
- __test__ attribute on modules/classes/functions
- general usage of nose utilities

16.3 Unsupported idioms / known issues

- unittest-style setUp, tearDown, setUpClass, tearDownClass are recognized only on unittest.TestCase classes but not on plain classes. nose supports these methods also on plain classes but pytest deliberately does not. As nose and pytest already both support setup_class, teardown_class, setup_method, teardown_method it doesn't seem useful to duplicate the unittest-API like nose does. If you however rather think pytest should support the unittest-spelling on plain classes please post to this issue.
- nose imports test modules with the same import path (e.g. tests.test_mod) but different file system paths (e.g. tests/test_mode.py and other/tests/test_mode.py) by extending sys.path/import semantics. pytest does not do that but there is discussion in issue268 for adding some support. Note that nose2 choose to avoid this sys.path/import hackery.

- nose-style doctests are not collected and executed correctly, also doctest fixtures don't work.
- no nose-configuration is recognized.
- yield-based methods don't support setup properly because the setup method is always called in the same class instance. There are no plans to fix this currently because yield-tests are deprecated in pytest 3.0, with pytest.mark.parametrize being the recommended alternative.

classic xunit-style setup

This section describes a classic and popular way how you can implement fixtures (setup and teardown test state) on a per-module/class/function basis.

Note: While these setup/teardown methods are simple and familiar to those coming from a unittest or nose background, you may also consider using pytest's more powerful *fixture mechanism* which leverages the concept of dependency injection, allowing for a more modular and more scalable approach for managing test state, especially for larger projects and for functional testing. You can mix both fixture mechanisms in the same file but test methods of unittest. TestCase subclasses cannot receive fixture arguments.

17.1 Module level setup/teardown

If you have multiple test functions and test classes in a single module you can optionally implement the following fixture methods which will usually be called once for all the functions:

```
def setup_module(module):
    """ setup any state specific to the execution of the given module."""

def teardown_module(module):
    """ teardown any state that was previously setup with a setup_module
    method.
    """
```

As of pytest-3.0, the module parameter is optional.

17.2 Class level setup/teardown

Similarly, the following methods are called at class level before and after all test methods of the class are called:

```
@classmethod
def setup_class(cls):
    """ setup any state specific to the execution of the given class (which
    usually contains tests).
    """
@classmethod
def teardown_class(cls):
    """ teardown any state that was previously setup with a call to
```

```
setup_class.
```

17.3 Method and function level setup/teardown

Similarly, the following methods are called around each method invocation:

```
def setup_method(self, method):
    """ setup any state tied to the execution of the given method in a
    class. setup_method is invoked for every test method of a class.
    """

def teardown_method(self, method):
    """ teardown any state that was previously setup with a setup_method
    call.
    """
```

As of pytest-3.0, the method parameter is optional.

If you would rather define test functions directly at module level you can also use the following functions to implement fixtures:

```
def setup_function(function):
    """ setup any state tied to the execution of the given function.
    Invoked for every test function in the module.
    """

def teardown_function(function):
    """ teardown any state that was previously setup with a setup_function call.
    """
```

As of pytest-3.0, the function parameter is optional.

Remarks:

- It is possible for setup/teardown pairs to be invoked multiple times per testing process.
- teardown functions are not called if the corresponding setup function existed and failed/was skipped.

Installing and Using plugins

This section talks about installing and using third party plugins. For writing your own plugins, please refer to *Writing plugins*.

Installing a third party plugin can be easily done with pip:

```
pip install pytest-NAME
pip uninstall pytest-NAME
```

If a plugin is installed, pytest automatically finds and integrates it, there is no need to activate it.

Here is a little annotated list for some popular plugins:

- pytest-django: write tests for django apps, using pytest integration.
- pytest-twisted: write tests for twisted apps, starting a reactor and processing deferreds from test functions.
- pytest-catchlog: to capture and assert about messages from the logging module
- pytest-cov: coverage reporting, compatible with distributed testing
- pytest-xdist: to distribute tests to CPUs and remote hosts, to run in boxed mode which allows to survive segmentation faults, to run in looponfailing mode, automatically re-running failing tests on file changes.
- pytest-instafail: to report failures while the test run is happening.
- pytest-bdd and pytest-konira to write tests using behaviour-driven testing.
- pytest-timeout: to timeout tests based on function marks or global definitions.
- pytest-pep8: a --pep8 option to enable PEP8 compliance checking.
- pytest-flakes: check source code with pyflakes.
- oejskit: a plugin to run javascript unittests in live browsers.

To see a complete list of all plugins with their latest testing status against different pytest and Python versions, please visit plugincompat.

You may also discover more plugins through a pytest-pypi.python.org search.

18.1 Requiring/Loading plugins in a test module or conftest file

You can require plugins in a test module or a conftest file like this:

```
pytest_plugins = "myapp.testsupport.myplugin",
```

When the test module or conftest plugin is loaded the specified plugins will be loaded as well.

```
pytest_plugins = "myapp.testsupport.myplugin"
```

which will import the specified module as a pytest plugin.

18.2 Finding out which plugins are active

If you want to find out which plugins are active in your environment you can type:

```
pytest --trace-config
```

and will get an extended test header which shows activated plugins and their names. It will also print local plugins aka *conftest.py* files when they are loaded.

18.3 Deactivating / unregistering a plugin by name

You can prevent plugins from loading or unregister them:

```
pytest -p no:NAME
```

This means that any subsequent try to activate/load the named plugin will not work.

If you want to unconditionally disable a plugin for a project, you can add this option to your pytest.ini file:

```
[pytest]
addopts = -p no:NAME
```

Alternatively to disable it only in certain environments (for example in a CI server), you can set PYTEST_ADDOPTS environment variable to -p no:name.

See *Finding out which plugins are active* for how to obtain the name of a plugin.

18.4 Pytest default plugin reference

You can find the source code for the following plugins in the pytest repository.

_pytest.assertion	support for presenting detailed information in failing assertions.
_pytest.cacheprovider	merged implementation of the cache provider
_pytest.capture	per-test stdout/stderr capturing mechanism.
_pytest.config	command line options, ini-file and conftest.py processing.
_pytest.doctest	discover and run doctests in modules and test files.
_pytest.helpconfig	version info, help messages, tracing configuration.
_pytest.junitxml	report test results in JUnit-XML format,
_pytest.mark	generic mechanism for marking and selecting python functions.
_pytest.monkeypatch	monkeypatching and mocking functionality.
_pytest.nose	run test suites written for nose.
_pytest.pastebin	submit failure or test session information to a pastebin service.
_pytest.debugging	interactive debugging with PDB, the Python Debugger.
_pytest.pytester	(disabled by default) support for testing pytest and pytest plugins.
_pytest.python	Python test discovery, setup and run of test functions.
	Continued on next page

Table 18.1 – continued from previous page

_pytest.recwarn	recording warnings during test function execution.
_pytest.resultlog	log machine-parseable test session result information in a plain
_pytest.runner	basic collect and runtest protocol implementations
_pytest.main	core implementation of testing process: init, session, runtest loop.
_pytest.skipping	support for skip/xfail functions and markers.
_pytest.terminal	terminal reporting of the full testing process.
_pytest.tmpdir	support for providing temporary directories to test functions.
_pytest.unittest	discovery and running of std-library "unittest" style tests.

Writing plugins

It is easy to implement *local conftest plugins* for your own project or *pip-installable plugins* that can be used throughout many projects, including third party projects. Please refer to *Installing and Using plugins* if you only want to use but not write plugins.

A plugin contains one or multiple hook functions. *Writing hooks* explains the basics and details of how you can write a hook function yourself. pytest implements all aspects of configuration, collection, running and reporting by calling *well specified hooks* of the following plugins:

- Pytest default plugin reference: loaded from pytest's internal _pytest directory.
- external plugins: modules discovered through setuptools entry points
- · conftest.py plugins: modules auto-discovered in test directories

In principle, each hook call is a 1:N Python function call where N is the number of registered implementation functions for a given specification. All specifications and implementations follow the pytest_ prefix naming convention, making them easy to distinguish and find.

19.1 Plugin discovery order at tool startup

pytest loads plugin modules at tool startup in the following way:

- by loading all builtin plugins
- by loading all plugins registered through setuptools entry points.
- by pre-scanning the command line for the -p name option and loading the specified plugin before actual command line parsing.
- by loading all conftest.py files as inferred by the command line invocation:
 - if no test paths are specified use current dir as a test path
 - if exists, load conftest.py and test*/conftest.py relative to the directory part of the first test
 path.

Note that pytest does not find conftest.py files in deeper nested sub directories at tool startup. It is usually a good idea to keep your conftest.py file in the top level test or project root directory.

• by recursively loading all plugins specified by the pytest plugins variable in conftest.py files

19.2 conftest.py: local per-directory plugins

Local conftest.py plugins contain directory-specific hook implementations. Hook Session and test running activities will invoke all hooks defined in conftest.py files closer to the root of the filesystem. Example of implementing the pytest_runtest_setup hook so that is called for tests in the a sub directory but not for other directories:

```
a/conftest.py:
    def pytest_runtest_setup(item):
        # called for running each test in 'a' directory
        print ("setting up", item)

a/test_sub.py:
    def test_sub():
        pass

test_flat.py:
    def test_flat():
        pass
```

Here is how you might run it:

```
pytest test_flat.py  # will not show "setting up"
pytest a/test_sub.py  # will show "setting up"
```

Note: If you have conftest.py files which do not reside in a python package directory (i.e. one containing an __init__.py) then "import conftest" can be ambiguous because there might be other conftest.py files as well on your PYTHONPATH or sys.path. It is thus good practice for projects to either put conftest.py under a package scope or to never import anything from a conftest.py file.

19.3 Writing your own plugin

If you want to write a plugin, there are many real-life examples you can copy from:

- a custom collection example plugin: A basic example for specifying tests in Yaml files
- around 20 Pytest default plugin reference which provide pytest's own functionality
- many external plugins providing additional features

All of these plugins implement the documented well specified hooks to extend and add functionality.

Note: Make sure to check out the excellent cookiecutter-pytest-plugin project, which is a cookiecutter template for authoring plugins.

The template provides an excellent starting point with a working plugin, tests running with tox, comprehensive README and entry-pointy already pre-configured.

Also consider contributing your plugin to pytest-dev once it has some happy users other than yourself.

19.4 Making your plugin installable by others

If you want to make your plugin externally available, you may define a so-called entry point for your distribution so that pytest finds your plugin module. Entry points are a feature that is provided by setuptools. pytest looks up the pytest11 entrypoint to discover its plugins and you can thus make your plugin available by defining it in your setuptools-invocation:

If a package is installed this way, pytest will load myproject.pluginmodule as a plugin which can define well specified hooks.

Note: Make sure to include Framework :: Pytest in your list of PyPI classifiers to make it easy for users to find your plugin.

19.5 Assertion Rewriting

One of the main features of pytest is the use of plain assert statements and the detailed introspection of expressions upon assertion failures. This is provided by "assertion rewriting" which modifies the parsed AST before it gets compiled to bytecode. This is done via a PEP 302 import hook which gets installed early on when pytest starts up and will perform this re-writing when modules get imported. However since we do not want to test different bytecode then you will run in production this hook only re-writes test modules themselves as well as any modules which are part of plugins. Any other imported module will not be re-written and normal assertion behaviour will happen.

If you have assertion helpers in other modules where you would need assertion rewriting to be enabled you need to ask pytest explicitly to re-write this module before it gets imported.

```
register_assert_rewrite(*names)
```

Register a module name to be rewritten on import.

This function will make sure that this module or all modules inside the package will get their assert statements rewritten. Thus you should make sure to call this before the module is actually imported, usually in your __init__.py if you are a plugin using a package.

Raises TypeError – if the given module names are not strings.

This is especially important when you write a pytest plugin which is created using a package. The import hook only treats conftest.py files and any modules which are listed in the pytest11 entrypoint as plugins. As an example consider the following package:

```
pytest_foo/__init__.py
pytest_foo/plugin.py
pytest_foo/helper.py
```

With the following typical setup.py extract:

```
setup(
    ...
    entry_points={'pytest11': ['foo = pytest_foo.plugin']},
    ...
)
```

In this case only pytest_foo/plugin.py will be re-written. If the helper module also contains assert statements which need to be re-written it needs to be marked as such, before it gets imported. This is easiest by marking it for re-writing inside the __init__.py module, which will always be imported first when a module inside a package is imported. This way plugin.py can still import helper.py normally. The contents of pytest_foo/__init__.py will then need to look like this:

```
import pytest
pytest.register_assert_rewrite('pytest_foo.helper')
```

19.6 Requiring/Loading plugins in a test module or conftest file

You can require plugins in a test module or a conftest file like this:

```
pytest_plugins = "name1", "name2",
```

When the test module or conftest plugin is loaded the specified plugins will be loaded as well. You can also use dotted path like this:

```
pytest_plugins = "myapp.testsupport.myplugin"
```

which will import the specified module as a pytest plugin.

Plugins imported like this will automatically be marked to require assertion rewriting using the <code>pytest.register_assert_rewrite()</code> mechanism. However for this to have any effect the module must not be imported already, it it was already imported at the time the <code>pytest_plugins</code> statement is processed a warning will result and assertions inside the plugin will not be re-written. To fix this you can either call <code>pytest.register_assert_rewrite()</code> yourself before the module is imported, or you can arrange the code to delay the importing until after the plugin is registered.

19.7 Accessing another plugin by name

If a plugin wants to collaborate with code from another plugin it can obtain a reference through the plugin manager like this:

```
plugin = config.pluginmanager.getplugin("name_of_plugin")
```

If you want to look at the names of existing plugins, use the --trace-config option.

19.8 Testing plugins

pytest comes with some facilities that you can enable for testing your plugin. Given that you have an installed plugin you can enable the <code>testdir</code> fixture via specifying a command line option to include the pytester plugin (-p pytester) or by putting <code>pytest_plugins = "pytester"</code> into your test or <code>conftest.py</code> file. You then will have a <code>testdir</code> fixture which you can use like this:

```
# content of test_myplugin.py

pytest_plugins = "pytester"  # to get testdir fixture

def test_myplugin(testdir):
    testdir.makepyfile("""
        def test_example():
            pass
    """)
    result = testdir.runpytest("--verbose")
    result.stdout.fnmatch_lines("""
        test_example*
    """)
```

Note that by default testdir.runpytest() will perform a pytest in-process. You can pass the command line option --runpytest=subprocess to have it happen in a subprocess.

Also see the RunResult for more methods of the result object that you get from a call to runpytest.

Writing hook functions

20.1 hook function validation and execution

pytest calls hook functions from registered plugins for any given hook specification. Let's look at a typical hook function for the pytest_collection_modifyitems(session, config, items) hook which pytest calls after collection of all test items is completed.

When we implement a pytest_collection_modifyitems function in our plugin pytest will during registration verify that you use argument names which match the specification and bail out if not.

Let's look at a possible implementation:

```
def pytest_collection_modifyitems(config, items):
    # called after collection is completed
    # you can modify the ``items`` list
```

Here, pytest will pass in config (the pytest config object) and items (the list of collected test items) but will not pass in the session argument because we didn't list it in the function signature. This dynamic "pruning" of arguments allows pytest to be "future-compatible": we can introduce new hook named parameters without breaking the signatures of existing hook implementations. It is one of the reasons for the general long-lived compatibility of pytest plugins.

Note that hook functions other than pytest_runtest_* are not allowed to raise exceptions. Doing so will break the pytest run.

20.2 firstresult: stop at first non-None result

Most calls to pytest hooks result in a list of results which contains all non-None results of the called hook functions.

Some hook specifications use the firstresult=True option so that the hook call only executes until the first of N registered functions returns a non-None result which is then taken as result of the overall hook call. The remaining hook functions will not be called in this case.

20.3 hookwrapper: executing around other hooks

New in version 2.7.

pytest plugins can implement hook wrappers which wrap the execution of other hook implementations. A hook wrapper is a generator function which yields exactly once. When pytest invokes hooks it first executes hook wrappers and passes the same arguments as to the regular hooks.

At the yield point of the hook wrapper pytest will execute the next hook implementations and return their result to the yield point in the form of a Calloutcome instance which encapsulates a result or exception info. The yield point itself will thus typically not raise exceptions (unless there are bugs).

Here is an example definition of a hook wrapper:

```
import pytest

@pytest.hookimpl(hookwrapper=True)
def pytest_pyfunc_call(pyfuncitem):
    # do whatever you want before the next hook executes

outcome = yield
    # outcome.excinfo may be None or a (cls, val, tb) tuple

res = outcome.get_result() # will raise if outcome was exception
    # postprocess result
```

Note that hook wrappers don't return results themselves, they merely perform tracing or other side effects around the actual hook implementations. If the result of the underlying hook is a mutable object, they may modify that result but it's probably better to avoid it.

20.4 Hook function ordering / call example

For any given hook specification there may be more than one implementation and we thus generally view hook execution as a 1:N function call where N is the number of registered functions. There are ways to influence if a hook implementation comes before or after others, i.e. the position in the N-sized list of functions:

```
# Plugin 1
@pytest.hookimpl(tryfirst=True)
def pytest_collection_modifyitems(items):
    # will execute as early as possible

# Plugin 2
@pytest.hookimpl(trylast=True)
def pytest_collection_modifyitems(items):
    # will execute as late as possible

# Plugin 3
@pytest.hookimpl(hookwrapper=True)
def pytest_collection_modifyitems(items):
    # will execute even before the tryfirst one above!
    outcome = yield
    # will execute after all non-hookwrappers executed
```

Here is the order of execution:

- 1. Plugin3's pytest_collection_modifyitems called until the yield point because it is a hook wrapper.
- 2. Plugin1's pytest_collection_modifyitems is called because it is marked with tryfirst=True.
- 3. Plugin2's pytest_collection_modifyitems is called because it is marked with trylast=True (but even without this mark it would come after Plugin1).

4. Plugin3's pytest_collection_modifyitems then executing the code after the yield point. The yield receives a Calloutcome instance which encapsulates the result from calling the non-wrappers. Wrappers shall not modify the result.

It's possible to use tryfirst and trylast also in conjunction with hookwrapper=True in which case it will influence the ordering of hookwrappers among each other.

20.5 Declaring new hooks

Plugins and conftest.py files may declare new hooks that can then be implemented by other plugins in order to alter behaviour or interact with the new plugin:

```
pytest_addhooks (pluginmanager)
```

called at plugin registration time to allow adding new hooks via a call to pluginman-ager.add_hookspecs(module_or_class, prefix).

Hooks are usually declared as do-nothing functions that contain only documentation describing when the hook will be called and what return values are expected.

For an example, see newhooks.py from xdist.

20.6 Optionally using hooks from 3rd party plugins

Using new hooks from plugins as explained above might be a little tricky because of the standard *validation mechanism*: if you depend on a plugin that is not installed, validation will fail and the error message will not make much sense to your users.

One approach is to defer the hook implementation to a new plugin instead of declaring the hook functions directly in your plugin module, for example:

This has the added benefit of allowing you to conditionally install hooks depending on which plugins are installed.

pytest hook reference

21.1 Initialization, command line and configuration hooks

pytest_load_initial_conftests (early_config, parser, args)

implements the loading of initial conftest files ahead of command line option parsing.

pytest_cmdline_preparse(config, args)

(deprecated) modify command line arguments before option parsing.

pytest_cmdline_parse (pluginmanager, args)

return initialized config object, parsing the specified args.

pytest_namespace()

return dict of name->object to be made globally available in the pytest namespace. This hook is called at plugin registration time.

pytest_addoption (parser)

register argparse-style options and ini-style config values, called once at the beginning of a test run.

Note: This function should be implemented only in plugins or conftest.py files situated at the tests root directory due to how pytest *discovers plugins during startup*.

Parameters parser – To add command line options, call parser.addoption(...). To add ini-file values call parser.addini(...).

Options can later be accessed through the *config* object, respectively:

- •config.getoption (name) to retrieve the value of a command line option.
- •config.getini (name) to retrieve a value read from an ini-style file.

The config object is passed around on many internal objects via the .config attribute or can be retrieved as the pytestconfig fixture or accessed via (deprecated) pytest.config.

pytest cmdline main(config)

called for performing the main command line action. The default implementation will invoke the configure hooks and runtest_mainloop.

pytest_configure (config)

called after command line options have been parsed and all plugins and initial conftest files been loaded. This hook is called for every plugin.

pytest_unconfigure (config)

called before test process is exited.

21.2 Generic "runtest" hooks

All runtest related hooks receive a pytest. Item object.

pytest_runtest_protocol (item, nextitem)

implements the runtest_setup/call/teardown protocol for the given test item, including capturing exceptions and calling reporting hooks.

Parameters

- item test item for which the runtest protocol is performed.
- **nextitem** the scheduled-to-be-next test item (or None if this is the end my friend). This argument is passed on to pytest runtest teardown().

Return boolean True if no further hook implementations should be invoked.

pytest_runtest_setup(item)

called before pytest_runtest_call(item).

pytest_runtest_call (item)

called to execute the test item.

pytest_runtest_teardown (item, nextitem)

called after pytest_runtest_call.

Parameters nextitem – the scheduled-to-be-next test item (None if no further test item is scheduled). This argument can be used to perform exact teardowns, i.e. calling just enough finalizers so that nextitem only needs to call setup-functions.

pytest_runtest_makereport (item, call)

```
return a _pytest.runner.TestReport object for the given pytest.Item and
_pytest.runner.CallInfo.
```

For deeper understanding you may look at the default implementation of these hooks in _pytest.runner and maybe also in _pytest.pdb which interacts with _pytest.capture and its input/output capturing in order to immediately drop into interactive debugging when a test failure occurs.

The _pytest.terminal reported specifically uses the reporting hook to print information about a test run.

21.3 Collection hooks

pytest calls the following hooks for collecting files and directories:

pytest_ignore_collect (path, config)

return True to prevent considering this path for collection. This hook is consulted for all files and directories prior to calling more specific hooks.

pytest_collect_directory (path, parent)

called before traversing a directory for collection files.

pytest_collect_file (path, parent)

return collection Node or None for the given path. Any new node needs to have the specified parent as a parent.

For influencing the collection of objects in Python modules you can use the following hook:

pytest_pycollect_makeitem(collector, name, obj)

return custom item/collector for a python object in a module, or None.

pytest_generate_tests (metafunc)

generate (multiple) parametrized calls to a test function.

pytest_make_parametrize_id (config, val)

Return a user-friendly string representation of the given val that will be used by @pytest.mark.parametrize calls. Return None if the hook doesn't know about val.

After collection is complete, you can modify the order of items, delete or otherwise amend the test items:

pytest_collection_modifyitems (session, config, items)

called after collection has been performed, may filter or re-order the items in-place.

21.4 Reporting hooks

Session related reporting hooks:

pytest_collectstart (collector)

collector starts collecting.

pytest_itemcollected(item)

we just collected a test item.

pytest_collectreport (report)

collector finished collecting.

pytest_deselected(items)

called for test items deselected by keyword.

pytest_report_header (config, startdir)

return a string to be displayed as header info for terminal reporting.

${\tt pytest_report_teststatus}\ (\textit{report})$

return result-category, shortletter and verbose word for reporting.

pytest_terminal_summary (terminalreporter, exitstatus)

add additional section in terminal summary reporting.

pytest_fixture_setup (fixturedef, request)

performs fixture setup execution.

pytest fixture post finalizer(fixturedef)

called after fixture teardown, but before the cache is cleared so the fixture result cache fixturedef.cached_result can still be accessed.

And here is the central hook for reporting about test execution:

pytest_runtest_logreport (report)

process a test setup/call/teardown report relating to the respective phase of executing a test.

You can also use this hook to customize assertion representation for some types:

pytest_assertrepr_compare (config, op, left, right)

return explanation for comparisons in failing assert expressions.

Return None for no custom explanation, otherwise return a list of strings. The strings will be joined by newlines but any newlines *in* a string will be escaped. Note that all but the first line will be indented slightly, the intention is for the first line to be a summary.

21.5 Debugging/Interaction hooks

There are few hooks which can be used for special reporting or interaction with exceptions:

pytest_internalerror(excrepr, excinfo)

called for internal errors.

pytest_keyboard_interrupt (excinfo)

called for keyboard interrupt.

pytest_exception_interact (node, call, report)

called when an exception was raised which can potentially be interactively handled.

This hook is only called if an exception was raised that is not an internal exception like skip. Exception.

pytest_enter_pdb (config)

called upon pdb.set_trace(), can be used by plugins to take special action just before the python debugger enters in interactive mode.

Parameters config (_pytest.config.Config) - pytest config object

Reference of objects involved in hooks

class Config

access to configuration values, pluginmanager and plugin hooks.

option = None

access to command line option as attributes. (deprecated), use getoption() instead

pluginmanager = None

a pluginmanager instance

add_cleanup(func)

Add a function to be called when the config object gets out of use (usually coninciding with pytest_unconfigure).

warn (code, message, fslocation=None)

generate a warning for this test session.

classmethod fromdictargs (option_dict, args)

constructor useable for subprocesses.

addinivalue_line (name, line)

add a line to an ini-file option. The option must have been declared but might not yet be set in which case the line becomes the the first line in its value.

getini(name)

return configuration value from an *ini file*. If the specified name hasn't been registered through a prior parser.addini call (usually from a plugin), a ValueError is raised.

getoption (name, default=<NOTSET>, skip=False)

return command line option value.

Parameters

- name name of the option. You may also specify the literal ——OPT option instead of the "dest" option name.
- **default** default value if no option of that name exists.
- **skip** if True raise pytest.skip if option does not exists or has a None value.

getvalue (name, path=None)

(deprecated, use getoption())

getvalueorskip (name, path=None)

(deprecated, use getoption(skip=True))

class Parser

Parser for command line arguments and ini-file values.

Variables extra_info – dict of generic param -> value to display in case there's an error processing the command line arguments.

```
getgroup (name, description='', after=None)
```

get (or create) a named option Group.

Name name of the option group.

Description long description for –help output.

After name of other group, used for ordering -help output.

The returned group object has an addoption method with the same signature as parser.addoption but will be shown in the respective group in the output of pytest. —help.

addoption (*opts, **attrs)

register a command line option.

Opts option names, can be short or long options.

Attrs same attributes which the add_option() function of the argparse library accepts.

After command line parsing options are available on the pytest config object via config.option.NAME where NAME is usually set by passing a dest attribute, for example addoption("--long", dest="NAME", ...).

parse_known_args (args, namespace=None)

parses and returns a namespace object with known arguments at this point.

parse_known_and_unknown_args (args, namespace=None)

parses and returns a namespace object with known arguments, and the remaining arguments unknown at this point.

addini (name, help, type=None, default=None)

register an ini-file option.

Name name of the ini-variable

Type type of the variable, can be pathlist, args, linelist or bool.

Default default value if no ini-file option exists but is queried.

The value of ini-variables can be retrieved via a call to config. getini (name).

class Node

base class for Collector and Item the test collection tree. Collector subclasses have children, Items are terminal nodes.

name = None

a unique name within the scope of the parent node

parent = None

the parent collector node.

config = None

the pytest config object

session = None

the session this node is part of

fspath = None

filesystem path where this node was collected from (can be None)

keywords = None

keywords/markers collected from all scopes

extra keyword matches = None

allow adding of extra keywords to use for matching

ihook

fspath sensitive hook proxy used to call pytest hooks

warn (code, message)

generate a warning with the given code and message for this item.

nodeid

a ::-separated string denoting its collection tree address.

listchain()

return list of all parent collectors up to self, starting from root of collection tree.

add_marker (marker)

dynamically add a marker object to the node.

marker can be a string or pytest.mark.* instance.

get_marker(name)

get a marker object from this node or None if the node doesn't have a marker with that name.

listextrakeywords()

Return a set of all extra keywords in self and any parents.

addfinalizer(fin)

register a function to be called when this node is finalized.

This method can only be called when this node is active in a setup chain, for example during self.setup().

getparent (cls)

get the next parent node (including ourself) which is an instance of the given class

class Collector

Bases: _pytest.main.Node

Collector instances create children through collect() and thus iteratively build a tree.

exception CollectError

```
Bases: exceptions. Exception
```

an error during collection, contains a custom message.

```
Collector.collect()
```

returns a list of children (items and collectors) for this collection node.

```
Collector.repr_failure(excinfo)
```

represent a collection failure.

class Item

Bases: _pytest.main.Node

a basic test invocation item. Note that for a single function there might be multiple test invocation items.

class Module

Bases: _pytest.main.File, _pytest.python.PyCollector

Collector for test classes and functions.

class Class

Bases: _pytest.python.PyCollector

Collector for test methods.

class Function

```
Bases: __pytest.python.FunctionMixin, __pytest.main.Item, __pytest.fixtures.FuncargnamesCompatAttr
```

a Function Item is responsible for setting up and executing a Python test function.

originalname = None

original function name, without any decorations (for example parametrization adds a "[...]" suffix to function names).

New in version 3.0.

function

underlying python 'function' object

runtest()

execute the underlying test function.

class FixtureDef

A container for a factory definition.

class CallInfo

Result/Exception info a function invocation.

when = None

context of invocation: one of "setup", "call", "teardown", "memocollect"

excinfo = None

None or ExceptionInfo object.

class TestReport

Basic test report object (also used for setup and teardown calls if they fail).

nodeid = None

normalized collection node id

location = None

a (filesystempath, lineno, domaininfo) tuple indicating the actual location of a test item - it might be different from the collected one e.g. if a method is inherited from a different module.

keywords = None

a name -> value dictionary containing all keywords and markers associated with a test invocation.

outcome = None

test outcome, always one of "passed", "failed", "skipped".

longrepr = None

None or a failure representation.

when = None

one of 'setup', 'call', 'teardown' to indicate runtest phase.

sections = None

list of pairs (str, str) of extra information which needs to marshallable. Used by pytest to add captured text from stdout and stderr, but may be used by other plugins to add arbitrary information to reports.

duration = None

time it took to run just the test

capstderr

Return captured text from stderr, if capturing is enabled

New in version 3.0.

capstdout

Return captured text from stdout, if capturing is enabled

New in version 3.0.

longreprtext

Read-only property that returns the full string representation of longrepr.

New in version 3.0.

class CallOutcome

Outcome of a function call, either an exception or a proper result. Calling the get_result method will return the result or reraise the exception raised when the function was called.

get_plugin_manager()

Obtain a new instance of the _pytest.config.PytestPluginManager, with default plugins already loaded.

This function can be used by integration with other tools, like hooking into pytest to run tests into an IDE.

class PytestPluginManager

```
Bases: _pytest.vendored_packages.pluggy.PluginManager
```

Overwrites pluggy.PluginManager to add pytest-specific functionality:

- •loading plugins from the command line, PYTEST_PLUGIN env variable and pytest_plugins global variables found in plugins being loaded;
- •conftest.py loading during start-up;

```
addhooks (module or class)
```

Deprecated since version 2.8.

Use pluggy.PluginManager.add_hookspecs() instead.

```
parse_hookimpl_opts (plugin, name)
parse_hookspec_opts (module_or_class, name)
```

register (plugin, name=None)

getplugin (name)

hasplugin (name)

Return True if the plugin with the given name is registered.

```
pytest_configure (config)
consider_preparse (args)
consider_pluginarg (arg)
consider_conftest (conftestmodule)
consider_env()
consider_module (mod)
import_plugin (modname)
```

class PluginManager

Core Pluginmanager class which manages registration of plugin objects and 1:N hook calling.

You can register new hooks by calling addhooks (module_or_class). You can register plugin objects (which contain hooks) by calling register (plugin). The Pluginmanager is initialized with a prefix that is searched for in the names of the dict of registered plugin objects. An optional excludefunc allows to blacklist names which are not considered as hooks despite a matching prefix.

For debugging purposes you can call <code>enable_tracing()</code> which will subsequently send debug information to the trace helper.

register (plugin, name=None)

Register a plugin and return its canonical name or None if the name is blocked from registering. Raise a ValueError if the plugin is already registered.

unregister (plugin=None, name=None)

unregister a plugin object and all its contained hook implementations from internal data structures.

set_blocked(name)

block registrations of the given name, unregister if already registered.

is_blocked(name)

return True if the name blogs registering plugins of that name.

add_hookspecs (module_or_class)

add new hook specifications defined in the given module_or_class. Functions are recognized if they have been decorated accordingly.

get plugins()

return the set of registered plugins.

is_registered(plugin)

Return True if the plugin is already registered.

get_canonical_name (plugin)

Return canonical name for a plugin object. Note that a plugin may be registered under a different name which was specified by the caller of register(plugin, name). To obtain the name of an registered plugin use get_name (plugin) instead.

get_plugin (name)

Return a plugin or None for the given name.

get_name (plugin)

Return name for registered plugin or None if not registered.

check_pending()

Verify that all hooks which have not been verified against a hook specification are optional, otherwise raise PluginValidationError

load_setuptools_entrypoints (entrypoint_name)

Load modules from querying the specified setuptools entrypoint name. Return the number of loaded plugins.

list_plugin_distinfo()

return list of distinfo/plugin tuples for all setuptools registered plugins.

list_name_plugin()

return list of name/plugin pairs.

get_hookcallers (plugin)

get all hook callers for the specified plugin.

add_hookcall_monitoring(before, after)

add before/after tracing functions for all hooks and return an undo function which, when called, will remove the added tracers.

before (hook_name, hook_impls, kwargs) will be called ahead of all hook calls and receive a hookcaller instance, a list of HookImpl instances and the keyword arguments for the hook call.

after (outcome, hook_name, hook_impls, kwargs) receives the same arguments as before but also a _CallOutcome `object which represents the result of the overall hook call.

enable tracing()

enable tracing of hook calls and return an undo function.

subset_hook_caller (name, remove_plugins)

Return a new _HookCaller instance for the named method which manages calls to all registered plugins except the ones from remove plugins.

class Testdir

Temporary test directory with tools to test/run pytest itself.

This is based on the tmpdir fixture but provides a number of methods which aid with testing pytest itself. Unless chdir() is used all methods will use tmpdir as current working directory.

Attributes:

Tmpdir The py.path.local instance of the temporary directory.

Plugins A list of plugins to use with parseconfig() and runpytest(). Initially this is an empty list but plugins can be added to the list. The type of items to add to the list depend on the method which uses them so refer to them for details.

makeconftest (source)

Write a contest.py file with 'source' as contents.

```
makepyfile (*args, **kwargs)
```

Shortcut for .makefile() with a .py extension.

runpytest_inprocess(*args, **kwargs)

Return result of running pytest in-process, providing a similar interface to what self.runpytest() provides.

```
runpytest (*args, **kwargs)
```

Run pytest inline or in a subprocess, depending on the command line option "-runpytest" and return a RunResult.

runpytest_subprocess (*args, **kwargs)

Run pytest as a subprocess with given arguments.

Any plugins added to the plugins list will added using the -p command line option. Additionally --basetemp is used put any temporary files and directories in a numbered directory prefixed with "runpytest-" so they do not conflict with the normal numberd pytest location for temporary files and directories.

Returns a RunResult.

class RunResult

The result of running a command.

Attributes:

Ret The return value.

Outlines List of lines captured from stdout.

Errlines List of lines captures from stderr.

Stdout LineMatcher of stdout, use stdout.str() to reconstruct stdout or the commonly used stdout.fnmatch_lines() method.

Stderrr LineMatcher of stderr.

Duration Duration in seconds.

parseoutcomes()

Return a dictionary of outcomestring->num from parsing the terminal output that the test process produced.

assert_outcomes (passed=0, skipped=0, failed=0)

assert that the specified outcomes appear with the respective numbers (0 means it didn't occur) in the text output from a test run.

class LineMatcher

Flexible matching of text.

This is a convenience class to test large texts like the output of commands.

The constructor takes a list of lines without their trailing newlines, i.e. text.splitlines().

str()

Return the entire original text.

fnmatch_lines_random(lines2)

Check lines exist in the output.

The argument is a list of lines which have to occur in the output, in any order. Each line can contain glob whildcards.

get_lines_after (fnline)

Return all lines following the given line in the text.

The given line can contain glob wildcards.

fnmatch_lines(lines2)

Search the text for matching lines.

The argument is a list of lines which have to match and can use glob wildcards. If they do not match an pytest.fail() is called. The matches and non-matches are also printed on stdout.

Usages and Examples

Here is a (growing) list of examples. *Contact* us if you need more examples or have questions. Also take a look at the *comprehensive documentation* which contains many example snippets as well. Also, pytest on stackoverflow.com often comes with example answers.

For basic examples, see

- Installation and Getting Started for basic introductory examples
- Asserting with the assert statement for basic assertion examples
- pytest fixtures: explicit, modular, scalable for basic fixture/setup examples
- Parametrizing fixtures and test functions for basic test function parametrization
- Support for unittest.TestCase / Integration of fixtures for basic unittest integration
- Running tests written for nose for basic nosetests integration

The following examples aim at various use cases you might encounter.

23.1 Demo of Python failure reports with pytest

Here is a nice run of several tens of failures and how pytest presents things (unfortunately not showing the nice colors here in the HTML that you get on the terminal - we are working on that):

```
_____ TestFailing.test_simple ____
self = <failure_demo.TestFailing object at 0xdeadbeef>
   def test_simple(self):
       def f():
          return 42
       def g():
          return 43
       assert f() == g()
       assert 42 == 43
       + where 42 = <function TestFailing.test_simple.<locals>.f at 0xdeadbeef>()
        + and 43 = <function TestFailing.test_simple.<locals>.g at 0xdeadbeef>()
failure_demo.py:29: AssertionError
______ TestFailing.test_simple_multiline _____
self = <failure_demo.TestFailing object at 0xdeadbeef>
   def test_simple_multiline(self):
       otherfunc_multi(
                42,
                6 * 9)
failure_demo.py:34:
a = 42, b = 54
   def otherfunc_multi(a,b):
      assert (a ==
              b)
      assert 42 == 54
failure_demo.py:12: AssertionError
 _____ TestFailing.test_not _____
self = <failure_demo.TestFailing object at 0xdeadbeef>
   def test_not(self):
       def f():
          return 42
       assert not f()
       assert not 42
       + where 42 = <function TestFailing.test_not.<locals>.f at 0xdeadbeef>()
failure_demo.py:39: AssertionError
  _____ TestSpecialisedExplanations.test_eq_text __
self = <failure_demo.TestSpecialisedExplanations object at 0xdeadbeef>
   def test_eq_text(self):
       assert 'spam' == 'eggs'
       assert 'spam' == 'eggs'
Ε
E
        - spam
Ε
        + eggs
```

```
failure_demo.py:43: AssertionError
   _____ TestSpecialisedExplanations.test_eq_similar_text _
self = <failure_demo.TestSpecialisedExplanations object at 0xdeadbeef>
   def test_eq_similar_text(self):
        assert 'foo 1 bar' == 'foo 2 bar'
        assert 'foo 1 bar' == 'foo 2 bar'
E

23.2 Basic patterns and examples

23.2.1 Pass different values to a test function, depending on command line options

Suppose we want to write a test that depends on a command line option. Here is a basic pattern to achieve this:

```
# content of test_sample.py
def test_answer(cmdopt):
    if cmdopt == "type1":
        print ("first")
    elif cmdopt == "type2":
        print ("second")
    assert 0 # to see what was printed
```

For this to work we need to add a command line option and provide the cmdopt through a fixture function:

Let's run this without supplying our new option:

And now with supplying a command line option:

You can see that the command line option arrived in our test. This completes the basic pattern. However, one often rather wants to process command line options outside of the test and rather pass in different or more complex objects.

23.2.2 Dynamically adding command line options

Through addopts you can statically add command line options for your project. You can also dynamically modify the command line arguments before they get processed:

```
# content of conftest.py
import sys
def pytest_cmdline_preparse(args):
    if 'xdist' in sys.modules: # pytest-xdist plugin
        import multiprocessing
        num = max(multiprocessing.cpu_count() / 2, 1)
        args[:] = ["-n", str(num)] + args
```

If you have the xdist plugin installed you will now always perform test runs using a number of subprocesses close to your CPU. Running in an empty directory with the above conftest.py:

```
$ pytest
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 0 items
====== no tests ran in 0.12 seconds ========
```

23.2.3 Control skipping of tests according to command line option

Here is a conftest.py file adding a --runslow command line option to control skipping of slow marked tests:

We can now write a test module like this:

```
# content of test_module.py
import pytest

slow = pytest.mark.skipif(
    not pytest.config.getoption("--runslow"),
    reason="need --runslow option to run"
)

def test_func_fast():
```

```
@slow
def test_func_slow():
    pass
```

and when running it will see a skipped "slow" test:

```
$ pytest -rs # "-rs" means report details on the little 's'
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items

test_module.py .s
====== short test summary info =======
SKIP [1] test_module.py:13: need --runslow option to run
====== 1 passed, 1 skipped in 0.12 seconds =======
```

Or run it including the slow marked test:

```
$ pytest --runslow
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items

test_module.py ..
====== 2 passed in 0.12 seconds =======
```

23.2.4 Writing well integrated assertion helpers

If you have a test helper function called from a test you can use the pytest.fail marker to fail a test with a certain message. The test support function will not show up in the traceback if you set the __tracebackhide__ option somewhere in the helper function. Example:

```
# content of test_checkconfig.py
import pytest
def checkconfig(x):
    __tracebackhide__ = True
    if not hasattr(x, "config"):
        pytest.fail("not configured: %s" %(x,))

def test_something():
    checkconfig(42)
```

The __tracebackhide__ setting influences pytest showing of tracebacks: the checkconfig function will not be shown unless the --full-trace command line option is specified. Let's run our little function:

```
$ pytest -q test_checkconfig.py
F
====== FAILURES ======
____ test_something ____
def test_something():
```

```
checkconfig(42)
E Failed: not configured: 42

test_checkconfig.py:8: Failed
1 failed in 0.12 seconds
```

If you only want to hide certain exceptions, you can set __tracebackhide__ to a callable which gets the <code>ExceptionInfo</code> object. You can for example use this to make sure unexpected exception types aren't hidden:

```
import operator
import pytest

class ConfigException(Exception):
    pass

def checkconfig(x):
    __tracebackhide__ = operator.methodcaller('errisinstance', ConfigException)
    if not hasattr(x, "config"):
        raise ConfigException("not configured: %s" %(x,))

def test_something():
    checkconfig(42)
```

This will avoid hiding the exception traceback on unrelated exceptions (i.e. bugs in assertion helpers).

23.2.5 Detect if running from within a pytest run

Usually it is a bad idea to make application code behave differently if called from a test. But if you absolutely must find out if your application code is running from a test you can do something like this:

```
# content of conftest.py

def pytest_configure(config):
    import sys
    sys._called_from_test = True

def pytest_unconfigure(config):
    del sys._called_from_test
```

and then check for the sys._called_from_test flag:

```
if hasattr(sys, '_called_from_test'):
    # called from within a test run
else:
    # called "normally"
```

accordingly in your application. It's also a good idea to use your own application module rather than sys for handling flag.

23.2.6 Adding info to test report header

It's easy to present extra information in a pytest run:

```
# content of conftest.py

def pytest_report_header(config):
    return "project deps: mylib-1.1"
```

which will add the string to the test header accordingly:

```
$ pytest
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
project deps: mylib-1.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 0 items
====== no tests ran in 0.12 seconds =======
```

It is also possible to return a list of strings which will be considered as several lines of information. You may consider config.getoption('verbose') in order to display more information if applicable:

```
# content of conftest.py

def pytest_report_header(config):
    if config.getoption('verbose') > 0:
        return ["info1: did you know that ...", "did you?"]
```

which will add info only when run with "-v":

```
$ pytest -v
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.5
cachedir: .cache
info1: did you know that ...
did you?
rootdir: $REGENDOC_TMPDIR, inifile:
collecting ... collected 0 items
====== no tests ran in 0.12 seconds =======
```

and nothing when run plainly:

```
$ pytest
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 0 items
====== no tests ran in 0.12 seconds =======
```

23.2.7 profiling test duration

If you have a slow running large test suite you might want to find out which tests are the slowest. Let's make an artificial test suite:

```
# content of test_some_are_slow.py
import time

def test_funcfast():
    pass

def test_funcslow1():
    time.sleep(0.1)

def test_funcslow2():
    time.sleep(0.2)
```

Now we can profile which test functions execute the slowest:

23.2.8 incremental testing - test steps

Sometimes you may have a testing situation which consists of a series of test steps. If one step fails it makes no sense to execute further steps as they are all expected to fail anyway and their tracebacks add no insight. Here is a simple confitest.py file which introduces an incremental marker which is to be used on classes:

```
# content of conftest.py

import pytest

def pytest_runtest_makereport(item, call):
    if "incremental" in item.keywords:
        if call.excinfo is not None:
            parent = item.parent
            parent._previousfailed = item

def pytest_runtest_setup(item):
    if "incremental" in item.keywords:
        previousfailed = getattr(item.parent, "_previousfailed", None)
        if previousfailed is not None:
            pytest.xfail("previous test failed (%s)" %previousfailed.name)
```

These two hook implementations work together to abort incremental-marked tests in a class. Here is a test module example:

```
# content of test_step.py

import pytest

@pytest.mark.incremental
class TestUserHandling:
    def test_login(self):
        pass
    def test_modification(self):
        assert 0
    def test_deletion(self):
        pass

def test_normal():
    pass
```

If we run this:

```
$ pytest -rx
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 4 items
test_step.py .Fx.
===== short test summary info ======
XFAIL test_step.py::TestUserHandling::()::test_deletion
 reason: previous test failed (test_modification)
====== FAILURES ======
     ___ TestUserHandling.test_modification _
self = <test_step.TestUserHandling object at 0xdeadbeef>
   def test_modification(self):
       assert 0
       assert 0
test_step.py:9: AssertionError
===== 1 failed, 2 passed, 1 xfailed in 0.12 seconds =======
```

We'll see that test_deletion was not executed because test_modification failed. It is reported as an "expected failure".

23.2.9 Package/Directory-level fixtures (setups)

If you have nested test directories, you can have per-directory fixture scopes by placing fixture functions in a conftest.py file in that directory You can use all types of fixtures including *autouse fixtures* which are the equivalent of xUnit's setup/teardown concept. It's however recommended to have explicit fixture references in your tests or test classes rather than relying on implicitly executing setup/teardown functions, especially if they are far away from the actual tests.

Here is a an example for making a db fixture available in a directory:

```
# content of a/conftest.py
import pytest

class DB:
    pass

@pytest.fixture(scope="session")
def db():
    return DB()
```

and then a test module in that directory:

```
# content of a/test_db.py
def test_a1(db):
    assert 0, db # to show value
```

another test module:

```
# content of a/test_db2.py
def test_a2(db):
    assert 0, db # to show value
```

and then a module in a sister directory which will not see the db fixture:

```
# content of b/test_error.py
def test_root(db): # no db here, will error out
    pass
```

We can run this:

```
$ pytest
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 7 items
test_step.py .Fx.
a/test_db.py F
a/test_db2.py F
b/test_error.py E
===== ERRORS ======
     __ ERROR at setup of test_root ___
file $REGENDOC_TMPDIR/b/test_error.py, line 1
def test_root(db): # no db here, will error out
       fixture 'db' not found
       available fixtures: cache, capfd, capsys, doctest_namespace, monkeypatch, pytestconfig, reco
       use 'pytest --fixtures [testpath]' for help on them.
$REGENDOC_TMPDIR/b/test_error.py:1
====== FAILURES ======
  _____ TestUserHandling.test_modification __
self = <test_step.TestUserHandling object at 0xdeadbeef>
   def test_modification(self):
      assert 0
       assert 0
test_step.py:9: AssertionError
 _____ test_a1 ____
db = <conftest.DB object at 0xdeadbeef>
   def test_a1(db):
       assert 0, db # to show value
       AssertionError: <conftest.DB object at 0xdeadbeef>
       assert 0
a/test_db.py:2: AssertionError
 db = <conftest.DB object at 0xdeadbeef>
   def test_a2(db):
       assert 0, db # to show value
       AssertionError: <conftest.DB object at 0xdeadbeef>
       assert 0
a/test_db2.py:2: AssertionError
===== 3 failed, 2 passed, 1 xfailed, 1 error in 0.12 seconds =======
```

The two test modules in the a directory see the same db fixture instance while the one test in the sister-directory b doesn't see it. We could of course also define a db fixture in that sister directory's conftest.py file. Note that each fixture is only instantiated if there is a test actually needing it (unless you use "autouse" fixture which are always executed ahead of the first test executing).

23.2.10 post-process test reports / failures

If you want to postprocess test reports and need access to the executing environment you can implement a hook that gets called when the test "report" object is about to be created. Here we write out all failing test calls and also access a fixture (if it was used by the test) in case you want to query/look at it during your post processing. In our case we just write some informations out to a failures file:

```
# content of conftest.py
import pytest
import os.path
@pytest.hookimpl(tryfirst=True, hookwrapper=True)
def pytest_runtest_makereport(item, call):
   # execute all other hooks to obtain the report object
   outcome = yield
   rep = outcome.get_result()
    # we only look at actual failing test calls, not setup/teardown
   if rep.when == "call" and rep.failed:
       mode = "a" if os.path.exists("failures") else "w"
       with open("failures", mode) as f:
            # let's also access a fixture for the fun of it
            if "tmpdir" in item.fixturenames:
                extra = " (%s)" % item.funcargs["tmpdir"]
            else:
                extra = ""
            f.write(rep.nodeid + extra + "\n")
```

if you then have failing tests:

```
# content of test_module.py
def test_fail1(tmpdir):
    assert 0
def test_fail2():
    assert 0
```

and run them:

```
$ pytest test_module.py
======= test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items

test_module.py FF
====== FAILURES =======
_____ test_fail1 _____

tmpdir = local('PYTEST_TMPDIR/test_fail10')
```

```
def test_fail1(tmpdir):
>          assert 0
E          assert 0

test_module.py:2: AssertionError
____ test_fail2 ____

          def test_fail2():
>          assert 0
E          assert 0

test_module.py:4: AssertionError
====== 2 failed in 0.12 seconds =======
```

you will have a "failures" file which contains the failing test ids:

```
$ cat failures
test_module.py::test_fail1 (PYTEST_TMPDIR/test_fail10)
test_module.py::test_fail2
```

23.2.11 Making test result information available in fixtures

If you want to make test result reports available in fixture finalizers here is a little example implemented via a local plugin:

```
# content of conftest.py
import pytest
@pytest.hookimpl(tryfirst=True, hookwrapper=True)
def pytest_runtest_makereport(item, call):
   # execute all other hooks to obtain the report object
   outcome = yield
   rep = outcome.get_result()
    # set an report attribute for each phase of a call, which can
    # be "setup", "call", "teardown"
    setattr(item, "rep_" + rep.when, rep)
@pytest.fixture
def something(request):
   yield
    # request.node is an "item" because we use the default
    # "function" scope
   if request.node.rep_setup.failed:
       print ("setting up a test failed!", request.node.nodeid)
   elif request.node.rep_setup.passed:
        if request.node.rep_call.failed:
            print ("executing test failed", request.node.nodeid)
```

if you then have failing tests:

```
# content of test_module.py
import pytest
```

```
@pytest.fixture
def other():
    assert 0

def test_setup_fails(something, other):
    pass

def test_call_fails(something):
    assert 0

def test_fail2():
    assert 0
```

and run it:

```
$ pytest -s test_module.py
====== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 3 items
test_module.py Esetting up a test failed! test_module.py::test_setup_fails
Fexecuting test failed test_module.py::test_call_fails
====== ERRORS ======
  _____ ERROR at setup of test_setup_fails __
   @pytest.fixture
   def other():
      assert 0
E
       assert 0
test_module.py:6: AssertionError
====== FAILURES ======
 _____ test_call_fails _____
something = None
   def test_call_fails(something):
       assert 0
       assert 0
test_module.py:12: AssertionError
   ____ test_fail2 _____
   def test_fail2():
      assert 0
Ε
       assert 0
test_module.py:15: AssertionError
====== 2 failed, 1 error in 0.12 seconds ======
```

You'll see that the fixture finalizers could use the precise reporting information.

23.2.12 Freezing pytest

If you freeze your application using a tool like PyInstaller in order to distribute it to your end-users, it is a good idea to also package your test runner and run your tests using the frozen application. This way packaging errors such as dependencies not being included into the executable can be detected early while also allowing you to send test files to users so they can run them in their machines, which can be useful to obtain more information about a hard to reproduce bug.

Fortunately recent PyInstaller releases already have a custom hook for pytest, but if you are using another tool to freeze executables such as <code>cx_freeze</code> or <code>py2exe</code>, you can use <code>pytest.freeze_includes()</code> to obtain the full list of internal pytest modules. How to configure the tools to find the internal modules varies from tool to tool, however.

Instead of freezing the pytest runner as a separate executable, you can make your frozen program work as the pytest runner by some clever argument handling during program startup. This allows you to have a single executable, which is usually more convenient.

```
# contents of app_main.py
import sys

if len(sys.argv) > 1 and sys.argv[1] == '--pytest':
    import pytest
    sys.exit(pytest.main(sys.argv[2:]))
else:
    # normal application execution: at this point argv can be parsed
    # by your argument-parsing library of choice as usual
    ...
```

This allows you to execute tests using the frozen application with standard pytest command-line options:

```
./app_main --pytest --verbose --tb=long --junitxml=results.xml test-suite/
```

23.3 Parametrizing tests

pytest allows to easily parametrize test functions. For basic docs, see *Parametrizing fixtures and test functions*. In the following we provide some examples using the builtin mechanisms.

23.3.1 Generating parameters combinations, depending on command line

Let's say we want to execute a test with different computation parameters and the parameter range shall be determined by a command line argument. Let's first write a simple (do-nothing) computation test:

```
# content of test_compute.py

def test_compute(param1):
    assert param1 < 4</pre>
```

Now we add a test configuration like this:

```
# content of conftest.py

def pytest_addoption(parser):
    parser.addoption("--all", action="store_true",
        help="run all combinations")
```

```
def pytest_generate_tests(metafunc):
    if 'param1' in metafunc.fixturenames:
        if metafunc.config.option.all:
            end = 5
        else:
            end = 2
        metafunc.parametrize("param1", range(end))
```

This means that we only run 2 tests if we do not pass --all:

```
$ pytest -q test_compute.py
..
2 passed in 0.12 seconds
```

We run only two computations, so we see two dots. let's run the full monty:

As expected when running the full range of param1 values we'll get an error on the last one.

23.3.2 Different options for test IDs

pytest will build a string that is the test ID for each set of values in a parametrized test. These IDs can be used with -k to select specific cases to run, and they will also identify the specific case when one is failing. Running pytest with --collect-only will show the generated IDs.

Numbers, strings, booleans and None will have their usual string representation used in the test ID. For other objects, pytest will make a string based on the argument name:

```
# content of test_time.py
import pytest
from datetime import datetime, timedelta

testdata = [
    (datetime(2001, 12, 12), datetime(2001, 12, 11), timedelta(1)),
    (datetime(2001, 12, 11), datetime(2001, 12, 12), timedelta(-1)),
]

@pytest.mark.parametrize("a,b,expected", testdata)
def test_timedistance_v0(a, b, expected):
    diff = a - b
    assert diff == expected
```

```
@pytest.mark.parametrize("a,b,expected", testdata, ids=["forward", "backward"])
def test_timedistance_v1(a, b, expected):
    diff = a - b
    assert diff == expected

def idfn(val):
    if isinstance(val, (datetime,)):
        # note this wouldn't show any hours/minutes/seconds
        return val.strftime('%Y%m%d')

@pytest.mark.parametrize("a,b,expected", testdata, ids=idfn)
def test_timedistance_v2(a, b, expected):
    diff = a - b
    assert diff == expected
```

In test_timedistance_v0, we let pytest generate the test IDs.

In test_timedistance_v1, we specified ids as a list of strings which were used as the test IDs. These are succinct, but can be a pain to maintain.

In test_timedistance_v2, we specified ids as a function that can generate a string representation to make part of the test ID. So our datetime values use the label generated by idfn, but because we didn't generate a label for timedelta objects, they are still using the default pytest representation:

23.3.3 A quick port of "testscenarios"

Here is a quick port to run tests configured with test scenarios, an add-on from Robert Collins for the standard unittest framework. We only have to work a bit to construct the correct arguments for pytest's <code>Metafunc.parametrize()</code>:

```
# content of test_scenarios.py

def pytest_generate_tests(metafunc):
    idlist = []
    argvalues = []
    for scenario in metafunc.cls.scenarios:
        idlist.append(scenario[0])
        items = scenario[1].items()
        argnames = [x[0] for x in items]
        argvalues.append(([x[1] for x in items]))
```

```
metafunc.parametrize(argnames, argvalues, ids=idlist, scope="class")
scenario1 = ('basic', {'attribute': 'value'})
scenario2 = ('advanced', {'attribute': 'value2'})

class TestSampleWithScenarios:
    scenarios = [scenario1, scenario2]

    def test_demo1(self, attribute):
        assert isinstance(attribute, str)

def test_demo2(self, attribute):
        assert isinstance(attribute, str)
```

this is a fully self-contained example which you can run with:

```
$ pytest test_scenarios.py
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 4 items
test_scenarios.py ....
====== 4 passed in 0.12 seconds =========
```

If you just collect tests you'll also nicely see 'advanced' and 'basic' as variants for the test function:

Note that we told metafunc.parametrize() that your scenario values should be considered class-scoped. With pytest-2.3 this leads to a resource-based ordering.

23.3.4 Deferring the setup of parametrized resources

The parametrization of test functions happens at collection time. It is a good idea to setup expensive resources like DB connections or subprocess only when the actual test is run. Here is a simple example how you can achieve that, first the actual test requiring a db object:

```
# content of test_backends.py
import pytest
def test_db_initialized(db):
    # a dummy test
```

```
if db.__class__.__name__ == "DB2":
    pytest.fail("deliberately failing for demo purposes")
```

We can now add a test configuration that generates two invocations of the test_db_initialized function and also implements a factory that creates a database object for the actual test invocations:

```
# content of conftest.py
import pytest
def pytest_generate_tests(metafunc):
    if 'db' in metafunc.fixturenames:
       metafunc.parametrize("db", ['d1', 'd2'], indirect=True)
class DB1:
    "one database object"
class DB2:
    "alternative database object"
@pytest.fixture
def db(request):
    if request.param == "d1":
        return DB1()
    elif request.param == "d2":
        return DB2()
    else:
        raise ValueError("invalid internal test config")
```

Let's first see how it looks like at collection time:

```
$ pytest test_backends.py --collect-only
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items
<Module 'test_backends.py'>
    <Function 'test_db_initialized[d1]'>
    <Function 'test_db_initialized[d2]'>
======= no tests ran in 0.12 seconds ========
```

And then when we run the test:

The first invocation with db == "DB1" passed while the second with db == "DB2" failed. Our db fixture func-

tion has instantiated each of the DB values during the setup phase while the pytest_generate_tests generated two according calls to the test_db_initialized during the collection phase.

23.3.5 Apply indirect on particular arguments

Very often parametrization uses more than one argument name. There is opportunity to apply indirect parameter on particular arguments. It can be done by passing list or tuple of arguments' names to indirect. In the example below there is a function test_indirect which uses two fixtures: x and y. Here we give to indirect the list, which contains the name of the fixture x. The indirect parameter will be applied to this argument only, and the value a will be passed to respective fixture function:

```
# content of test_indirect_list.py

import pytest
@pytest.fixture(scope='function')
def x(request):
    return request.param * 3

@pytest.fixture(scope='function')
def y(request):
    return request.param * 2

@pytest.mark.parametrize('x, y', [('a', 'b')], indirect=['x'])
def test_indirect(x,y):
    assert x == 'aaa'
    assert y == 'b'
```

The result of this test will be successful:

23.3.6 Parametrizing test methods through per-class configuration

Here is an example pytest_generate_function function implementing a parametrization scheme similar to Michael Foord's unittest parametrizer but in a lot less code:

```
params = {
    'test_equals': [dict(a=1, b=2), dict(a=3, b=3), ],
    'test_zerodivision': [dict(a=1, b=0), ],
}

def test_equals(self, a, b):
    assert a == b

def test_zerodivision(self, a, b):
    pytest.raises(ZeroDivisionError, "a/b")
```

Our test generator looks up a class-level definition which specifies which argument sets to use for each test function. Let's run it:

```
$ pytest -q
F..
====== FAILURES ======
_____ TestClass.test_equals[1-2] _____

self = <test_parametrize.TestClass object at 0xdeadbeef>, a = 1, b = 2

def test_equals(self, a, b):
> assert a == b
E assert 1 == 2

test_parametrize.py:18: AssertionError
1 failed, 2 passed in 0.12 seconds
```

23.3.7 Indirect parametrization with multiple fixtures

Here is a stripped down real-life example of using parametrized testing for testing serialization of objects between different python interpreters. We define a test_basic_objects function which is to be run with different sets of arguments for its three arguments:

- python1: first python interpreter, run to pickle-dump an object to a file
- python2: second interpreter, run to pickle-load an object from a file
- obj: object to be dumped/loaded

```
module containing a parametrized tests testing cross-python
serialization via the pickle module.
"""
import py
import pytest
import _pytest._code

pythonlist = ['python2.6', 'python2.7', 'python3.4', 'python3.5']
@pytest.fixture(params=pythonlist)
def python1(request, tmpdir):
    picklefile = tmpdir.join("data.pickle")
    return Python(request.param, picklefile)

@pytest.fixture(params=pythonlist)
def python2(request, python1):
    return Python(request.param, python1.picklefile)
```

```
class Python:
    def __init__(self, version, picklefile):
        self.pythonpath = py.path.local.sysfind(version)
        if not self.pythonpath:
            pytest.skip("%r not found" %(version,))
        self.picklefile = picklefile
    def dumps(self, obj):
        dumpfile = self.picklefile.dirpath("dump.py")
        dumpfile.write(_pytest._code.Source("""
            import pickle
            f = open(%r, 'wb')
            s = pickle.dump(%r, f, protocol=2)
            f.close()
        """ % (str(self.picklefile), obj)))
        py.process.cmdexec("%s %s" %(self.pythonpath, dumpfile))
    def load_and_is_true(self, expression):
        loadfile = self.picklefile.dirpath("load.py")
        loadfile.write(_pytest._code.Source("""
            import pickle
            f = open(%r, 'rb')
            obj = pickle.load(f)
            f.close()
            res = eval(%r)
            if not res:
                raise SystemExit(1)
        """ % (str(self.picklefile), expression)))
        print (loadfile)
        py.process.cmdexec("%s %s" %(self.pythonpath, loadfile))
@pytest.mark.parametrize("obj", [42, {}, {1:3},])
def test_basic_objects(python1, python2, obj):
    python1.dumps(obj)
    python2.load_and_is_true("obj == %s" % obj)
```

Running it results in some skips if we don't have all the python interpreters installed and otherwise runs all combinations (5 interpreters times 5 interpreters times 3 objects to serialize/deserialize):

```
. $ pytest -rs -q multipython.py
sssssssssssssssss.....sss......
====== short test summary info =======
SKIP [21] $REGENDOC_TMPDIR/CWD/multipython.py:23: 'python2.6' not found
27 passed, 21 skipped in 0.12 seconds
```

23.3.8 Indirect parametrization of optional implementations/imports

If you want to compare the outcomes of several implementations of a given API, you can write test functions that receive the already imported implementations and get skipped in case the implementation is not importable/available. Let's say we have a "base" implementation and the other (possibly optimized ones) need to provide similar results:

```
# content of conftest.py
import pytest
@pytest.fixture(scope="session")
def basemod(request):
    return pytest.importorskip("base")
```

```
@pytest.fixture(scope="session", params=["opt1", "opt2"])
def optmod(request):
    return pytest.importorskip(request.param)
```

And then a base implementation of a simple function:

```
# content of base.py
def func1():
    return 1
```

And an optimized version:

```
# content of opt1.py
def func1():
    return 1.0001
```

And finally a little test module:

```
# content of test_module.py

def test_func1(basemod, optmod):
    assert round(basemod.func1(), 3) == round(optmod.func1(), 3)
```

If you run this with reporting for skips enabled:

```
$ pytest -rs test_module.py
====== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 2 items

test_module.py .s
====== short test summary info =======
SKIP [1] $REGENDOC_TMPDIR/conftest.py:10: could not import 'opt2'
====== 1 passed, 1 skipped in 0.12 seconds =======
```

You'll see that we don't have a opt2 module and thus the second test run of our test_func1 was skipped. A few notes:

- the fixture functions in the conftest.py file are "session-scoped" because we don't need to import more than once
- if you have multiple test functions and a skipped import, you will see the [1] count increasing in the report
- you can put @pytest.mark.parametrize style parametrization on the test functions to parametrize input/output values as well.

23.4 Working with custom markers

Here are some example using the Marking test functions with attributes mechanism.

23.4.1 Marking test functions and selecting them for a run

You can "mark" a test function with custom metadata like this:

```
# content of test_server.py

import pytest
@pytest.mark.webtest
def test_send_http():
    pass # perform some webtest test for your app
def test_something_quick():
    pass
def test_another():
    pass
class TestClass:
    def test_method(self):
    pass
```

New in version 2.2.

You can then restrict a test run to only run tests marked with webtest:

Or the inverse, running all tests except the webtest ones:

23.4.2 Selecting tests based on their node ID

You can provide one or more *node IDs* as positional arguments to select only specified tests. This makes it easy to select tests based on their module, class, method, or function name:

```
$ pytest -v test_server.py::TestClass::test_method
====== test session starts ========
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.5
cachedir: .cache
rootdir: $REGENDOC_TMPDIR, inifile:
collecting ... collected 5 items
```

```
test_server.py::TestClass::test_method PASSED ====== 1 passed in 0.12 seconds =======
```

You can also select on the class:

```
$ pytest -v test_server.py::TestClass
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.2
cachedir: .cache
rootdir: $REGENDOC_TMPDIR, inifile:
collecting ... collected 4 items

test_server.py::TestClass::test_method PASSED
======= 1 passed in 0.12 seconds ========
```

Or select multiple nodes:

```
$ pytest -v test_server.py::TestClass test_server.py::test_send_http
======= test session starts ========
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.5
cachedir: .cache
rootdir: $REGENDOC_TMPDIR, inifile:
collecting ... collected 8 items

test_server.py::TestClass::test_method PASSED
test_server.py::test_send_http PASSED
======= 2 passed in 0.12 seconds ========
```

Note: Node IDs are of the form module.py::class::method or module.py::function. Node IDs control which tests are collected, so module.py::class will select all test methods on the class. Nodes are also created for each parameter of a parametrized fixture or test, so selecting a parametrized test must include the parameter value, e.g. module.py::function[param].

Node IDs for failing tests are displayed in the test summary info when running pytest with the -rf option. You can also construct Node IDs from the output of pytest --collectonly.

23.4.3 Using -k expr to select tests based on their name

You can use the -k command line option to specify an expression which implements a substring match on the test names instead of the exact match on markers that -m provides. This makes it easy to select tests based on their names:

And you can also run all tests except the ones that match the keyword:

Or to select "http" and "quick" tests:

Note: If you are using expressions such as "X and Y" then both X and Y need to be simple non-keyword names. For example, "pass" or "from" will result in SyntaxErrors because "-k" evaluates the expression.

However, if the "-k" argument is a simple string, no such restrictions apply. Also "-k 'not STRING" has no restrictions. You can also specify numbers like "-k 1.3" to match tests which are parametrized with the float "1.3".

23.4.4 Registering markers

New in version 2.2.

Registering markers for your test suite is simple:

```
# content of pytest.ini
[pytest]
markers =
   webtest: mark a test as a webtest.
```

You can ask which markers exist for your test suite - the list includes our just defined webtest markers:

```
$ pytest --markers
@pytest.mark.webtest: mark a test as a webtest.

@pytest.mark.skip(reason=None): skip the given test function with an optional reason. Example: skip(sepytest.mark.skipif(condition): skip the given test function if eval(condition) results in a True value.
```

```
@pytest.mark.xfail(condition, reason=None, run=True, raises=None, strict=False): mark the the test further depytest.mark.parametrize(argnames, argvalues): call a test function multiple times passing in different depytest.mark.usefixtures(fixturename1, fixturename2, ...): mark tests as needing all of the specified depytest.mark.tryfirst: mark a hook implementation function such that the plugin machinery will try to depytest.mark.trylast: mark a hook implementation function such that the plugin machinery will try to
```

For an example on how to add and work with markers from a plugin, see *Custom marker and command line option to control test runs*.

Note: It is recommended to explicitly register markers so that:

- there is one place in your test suite defining your markers
- asking for existing markers via pytest --markers gives good output
- typos in function markers are treated as an error if you use the --strict option. Future versions of pytest are probably going to start treating non-registered markers as errors at some point.

23.4.5 Marking whole classes or modules

You may use pytest.mark decorators with classes to apply markers to all of its test methods:

```
# content of test_mark_classlevel.py
import pytest
@pytest.mark.webtest
class TestClass:
    def test_startup(self):
        pass
    def test_startup_and_more(self):
        pass
```

This is equivalent to directly applying the decorator to the two test functions.

To remain backward-compatible with Python 2.4 you can also set a pytestmark attribute on a TestClass like this:

```
import pytest

class TestClass:
    pytestmark = pytest.mark.webtest
```

or if you need to use multiple markers you can use a list:

```
import pytest

class TestClass:
    pytestmark = [pytest.mark.webtest, pytest.mark.slowtest]
```

You can also set a module level marker:

```
import pytest
pytestmark = pytest.mark.webtest
```

in which case it will be applied to all functions and methods defined in the module.

23.4.6 Marking individual tests when using parametrize

When using parametrize, applying a mark will make it apply to each individual test. However it is also possible to apply a marker to an individual test instance:

In this example the mark "foo" will apply to each of the three tests, whereas the "bar" mark is only applied to the second test. Skip and xfail marks can also be applied in this way, see *Skip/xfail with parametrize*.

Note: If the data you are parametrizing happen to be single callables, you need to be careful when marking these items. *pytest.mark.xfail(my_func)* won't work because it's also the signature of a function being decorated. To resolve this ambiguity, you need to pass a reason argument: *pytest.mark.xfail(func_bar, reason="Issue#7")*.

23.4.7 Custom marker and command line option to control test runs

Plugins can provide custom markers and implement specific behaviour based on it. This is a self-contained example which adds a command line option and a parametrized test function marker to run tests specifies via named environments:

A test file using this local plugin:

```
# content of test_someenv.py
import pytest
@pytest.mark.env("stage1")
def test_basic_db_operation():
    pass
```

and an example invocations specifying a different environment than what the test needs:

```
$ pytest -E stage2
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 1 items
test_someenv.py s
====== 1 skipped in 0.12 seconds ========
```

and here is one that specifies exactly the environment needed:

```
$ pytest -E stage1
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 1 items

test_someenv.py .
====== 1 passed in 0.12 seconds ========
```

The --markers option always gives you a list of available markers:

```
$ pytest --markers
@pytest.mark.env(name): mark test to run only on named environment

@pytest.mark.skip(reason=None): skip the given test function with an optional reason. Example: skip()

@pytest.mark.skipif(condition): skip the given test function if eval(condition) results in a True val

@pytest.mark.xfail(condition, reason=None, run=True, raises=None, strict=False): mark the the test for

@pytest.mark.parametrize(argnames, argvalues): call a test function multiple times passing in difference to the second part of the specified () and the specified () arguments a possible to the specified () and the specified () arguments are the specified () and the specified () arguments are the specified () and the specified () arguments are the specified () and the specified () arguments are the specifie
```

23.4.8 Reading markers which were set from multiple places

If you are heavily using markers in your test suite you may encounter the case where a marker is applied several times to a test function. From plugin code you can read over all such settings. Example:

```
# content of test_mark_three_times.py
import pytest
pytestmark = pytest.mark.glob("module", x=1)

@pytest.mark.glob("class", x=2)
class TestClass:
    @pytest.mark.glob("function", x=3)
    def test_something(self):
        pass
```

Here we have the marker "glob" applied three times to the same test function. From a conftest file we can read it like this:

```
# content of conftest.py
import sys

def pytest_runtest_setup(item):
    g = item.get_marker("glob")
    if g is not None:
        for info in g:
            print ("glob args=%s kwargs=%s" %(info.args, info.kwargs))
            sys.stdout.flush()
```

Let's run this without capturing output and see what we get:

```
$ pytest -q -s
glob args=('function',) kwargs={'x': 3}
glob args=('class',) kwargs={'x': 2}
glob args=('module',) kwargs={'x': 1}
.
1 passed in 0.12 seconds
```

23.4.9 marking platform specific tests with pytest

Consider you have a test suite which marks tests for particular platforms, namely pytest.mark.darwin, pytest.mark.win32 etc. and you also have tests that run on all platforms and have no specific marker. If you now want to have a way to only run the tests for your particular platform, you could use the following plugin:

then tests will be skipped if they were specified for a different platform. Let's do a little test file to show how this looks like:

```
# content of test_plat.py
import pytest
@pytest.mark.darwin
def test_if_apple_is_evil():
    pass

@pytest.mark.linux2
def test_if_linux_works():
    pass

@pytest.mark.win32
```

```
def test_if_win32_crashes():
    pass

def test_runs_everywhere():
    pass
```

then you will see two test skipped and two executed tests as expected:

```
$ pytest -rs # this option reports skip reasons
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 4 items

test_plat.py sss.
====== short test summary info =======
SKIP [3] $REGENDOC_TMPDIR/conftest.py:12: cannot run on platform linux
====== 1 passed, 3 skipped in 0.12 seconds =======
```

Note that if you specify a platform via the marker-command line option like this:

```
$ pytest -m linux2
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 4 items

test_plat.py s
====== 3 tests deselected ========
===== 1 skipped, 3 deselected in 0.12 seconds =======
```

then the unmarked-tests will not be run. It is thus a way to restrict the run to the specific tests.

23.4.10 Automatically adding markers based on test names

If you a test suite where test function names indicate a certain type of test, you can implement a hook that automatically defines markers so that you can use the -m option with it. Let's look at this test module:

```
# content of test_module.py

def test_interface_simple():
    assert 0

def test_interface_complex():
    assert 0

def test_event_simple():
    assert 0

def test_something_else():
    assert 0
```

We want to dynamically define two markers and can do it in a conftest.py plugin:

```
# content of conftest.py
```

```
import pytest
def pytest_collection_modifyitems(items):
    for item in items:
        if "interface" in item.nodeid:
            item.add_marker(pytest.mark.interface)
        elif "event" in item.nodeid:
            item.add_marker(pytest.mark.event)
```

We can now use the -m option to select one set:

```
$ pytest -m interface --tb=short
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 4 items
test_module.py FF
====== FAILURES ======
     <u>    test_interface_simple  </u>
test_module.py:3: in test_interface_simple
   assert 0
  assert 0
    ___ test_interface_complex _
test_module.py:6: in test_interface_complex
   assert 0
  assert 0
====== 2 tests deselected ======
====== 2 failed, 2 deselected in 0.12 seconds =======
```

or to select both "event" and "interface" tests:

```
$ pytest -m "interface or event" --tb=short
===== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile:
collected 4 items
test_module.py FFF
====== FAILURES ======
      _ test_interface_simple
test_module.py:3: in test_interface_simple
   assert 0
E assert 0
      _ test_interface_complex _
test_module.py:6: in test_interface_complex
   assert 0
E assert 0
    ___ test_event_simple _
test_module.py:9: in test_event_simple
  assert 0
  assert 0
====== 1 tests deselected ======
===== 3 failed, 1 deselected in 0.12 seconds =======
```

23.5 A session-fixture which can look at all collected tests

A session-scoped fixture effectively has access to all collected test items. Here is an example of a fixture function which walks all collected tests and looks if their test class defines a callme method and calls it:

test classes may now define a callme method which will be called ahead of running any tests:

```
# content of test_module.py
class TestHello:
   @classmethod
    def callme(cls):
        print ("callme called!")
    def test_method1(self):
        print ("test_method1 called")
    def test_method2(self):
        print ("test_method1 called")
class TestOther:
   @classmethod
   def callme(cls):
        print ("callme other called")
    def test_other(self):
        print ("test other")
# works with unittest as well ...
import unittest
class SomeTest (unittest.TestCase):
    @classmethod
    def callme(self):
        print ("SomeTest callme called")
    def test_unit1(self):
        print ("test_unit1 method called")
```

If you run this without output capturing:

```
$ pytest -q -s test_module.py
callattr_ahead_of_alltests called
callme called!
```

```
callme other called
SomeTest callme called
test_method1 called
.test_method1 called
.test other
.test_unit1 method called
.
4 passed in 0.12 seconds
```

23.6 Changing standard (Python) test discovery

23.6.1 Ignore paths during test collection

You can easily ignore certain test directories and modules during collection by passing the --ignore=path option on the cli. pytest allows multiple --ignore options. Example:

Now if you invoke pytest with --ignore=tests/foobar/test_foobar_03.py --ignore=tests/hello/, you will see that pytest only collects test-modules, which do not match the patterns specified:

```
======= test session starts ======== platform darwin -- Python 2.7.10, pytest-2.8.2, py-1.4.30, pluggy-0.3.1 rootdir: $REGENDOC_TMPDIR, inifile: collected 5 items

tests/example/test_example_01.py . tests/example/test_example_02.py . tests/example/test_example_03.py . tests/foobar/test_foobar_01.py . tests/foobar/test_foobar_02.py .

====== 5 passed in 0.02 seconds ======
```

23.6.2 Keeping duplicate paths specified from command line

Default behavior of pytest is to ignore duplicate paths specified from the command line. Example:

```
py.test path_a path_a
```

```
collected 1 item
```

Just collect tests once.

To collect duplicate tests, use the --keep-duplicates option on the cli. Example:

```
py.test --keep-duplicates path_a path_a
...
collected 2 items
...
```

As the collector just works on directories, if you specify twice a single test file, pytest will still collect it twice, no matter if the --keep-duplicates is not specified. Example:

```
py.test test_a.py test_a.py
...
collected 2 items
...
```

23.6.3 Changing directory recursion

You can set the norecursedirs option in an ini-file, for example your pytest.ini in the project root directory:

```
# content of pytest.ini
[pytest]
norecursedirs = .svn _build tmp*
```

This would tell pytest to not recurse into typical subversion or sphinx-build directories or into any tmp prefixed directory.

23.6.4 Changing naming conventions

You can configure different naming conventions by setting the python_files, python_classes and python_functions configuration options. Example:

```
# content of pytest.ini
# can also be defined in in tox.ini or setup.cfg file, although the section
# name in setup.cfg files should be "tool:pytest"
[pytest]
python_files=check_*.py
python_classes=Check
python_functions=*_check
```

This would make pytest look for tests in files that match the <code>check_*</code> .py glob-pattern, <code>Check</code> prefixes in classes, and functions and methods that match <code>*_check</code>. For example, if we have:

```
# content of check_myapp.py
class CheckMyApp:
    def simple_check(self):
        pass
    def complex_check(self):
        pass
```

then the test collection looks like this:

Note: the python_functions and python_classes options has no effect for unittest.TestCase test discovery because pytest delegates detection of test case methods to unittest code.

23.6.5 Interpreting cmdline arguments as Python packages

You can use the --pyargs option to make pytest try interpreting arguments as python package names, deriving their file system path and then running the test. For example if you have unittest2 installed you can type:

```
pytest --pyargs unittest2.test.test_skipping -q
```

which would run the respective test module. Like with other options, through an ini-file and the addopts option you can make this change more permanently:

```
# content of pytest.ini
[pytest]
addopts = --pyargs
```

Now a simple invocation of pytest NAME will check if NAME exists as an importable package/module and otherwise treat it as a filesystem path.

23.6.6 Finding out what is collected

You can always peek at the collection tree without running tests like this:

23.6.7 customizing test collection to find all .py files

You can easily instruct pytest to discover tests from every python file:

```
# content of pytest.ini
[pytest]
python_files = *.py
```

However, many projects will have a setup.py which they don't want to be imported. Moreover, there may files only importable by a specific python version. For such cases you can dynamically define files to be ignored by listing them in a conftest.py file:

```
# content of conftest.py
import sys

collect_ignore = ["setup.py"]
if sys.version_info[0] > 2:
    collect_ignore.append("pkg/module_py2.py")
```

And then if you have a module file like this:

```
# content of pkg/module_py2.py
def test_only_on_python2():
    try:
        assert 0
    except Exception, e:
        pass
```

and a setup.py dummy file like this:

```
# content of setup.py
0/0 # will raise exception if imported
```

then a pytest run on Python2 will find the one test and will leave out the setup.py file:

```
#$ pytest --collect-only
====== test session starts =====
platform linux2 -- Python 2.7.10, pytest-2.9.1, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile: pytest.ini
collected 1 items
<Module 'pkg/module_py2.py'>
    <Function 'test_only_on_python2'>
====== no tests ran in 0.04 seconds ======
```

If you run with a Python3 interpreter both the one test and the setup.py file will be left out:

```
$ pytest --collect-only
====== test session starts ======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1
rootdir: $REGENDOC_TMPDIR, inifile: pytest.ini
collected 0 items
====== no tests ran in 0.12 seconds =======
```

23.7 Working with non-python tests

23.7.1 A basic example for specifying tests in Yaml files

Here is an example conftest.py (extracted from Ali Afshnars special purpose pytest-yamlwsgi plugin). This conftest.py will collect test*.yml files and will execute the yaml-formatted content as custom tests:

```
# content of conftest.py
import pytest
def pytest_collect_file(parent, path):
   if path.ext == ".yml" and path.basename.startswith("test"):
        return YamlFile(path, parent)
class YamlFile (pytest.File):
   def collect(self):
        import yaml # we need a yaml parser, e.g. PyYAML
        raw = yaml.safe_load(self.fspath.open())
        for name, spec in sorted(raw.items()):
            yield YamlItem(name, self, spec)
class YamlItem (pytest.Item):
    def __init__(self, name, parent, spec):
        super(YamlItem, self).__init__(name, parent)
        self.spec = spec
   def runtest(self):
        for name, value in sorted(self.spec.items()):
            # some custom test execution (dumb example follows)
            if name != value:
                raise YamlException(self, name, value)
   def repr_failure(self, excinfo):
        """ called when self.runtest() raises an exception. """
        if isinstance(excinfo.value, YamlException):
            return "\n".join([
                "usecase execution failed",
                  spec failed: %r: %r" % excinfo.value.args[1:3],
                  no further details known at this point."
            1)
   def reportinfo(self):
        return self.fspath, 0, "usecase: %s" % self.name
class YamlException(Exception):
    """ custom exception for error reporting. """
```

You can create a simple example file:

```
# test_simple.yml
ok:
    sub1: sub1
hello:
    world: world
    some: other
```

and if you installed PyYAML or a compatible YAML-parser you can now execute the test specification:

You get one dot for the passing sub1: sub1 check and one failure. Obviously in the above conftest.py you'll want to implement a more interesting interpretation of the yaml-values. You can easily write your own domain specific testing language this way.

Note: repr_failure(excinfo) is called for representing test failures. If you create custom collection nodes you can return an error representation string of your choice. It will be reported as a (red) string.

reportinfo() is used for representing the test location and is also consulted when reporting in verbose mode:

```
nonpython $ pytest -v
====== test session starts =======
platform linux -- Python 3.5.2, pytest-3.0.2, py-1.4.31, pluggy-0.3.1 -- $PYTHON_PREFIX/bin/python3.cachedir: .cache
rootdir: $REGENDOC_TMPDIR/nonpython, inifile:
collecting ... collected 2 items

test_simple.yml::hello FAILED
test_simple.yml::ok PASSED

====== FAILURES ======

___ usecase: hello ___
usecase execution failed
    spec failed: 'some': 'other'
    no further details known at this point.
====== 1 failed, 1 passed in 0.12 seconds =======
```

While developing your custom test collection and execution it's also interesting to just look at the collection tree:

Good Integration Practices

24.1 Conventions for Python test discovery

pytest implements the following standard test discovery:

- If no arguments are specified then collection starts from testpaths (if configured) or the current directory. Alternatively, command line arguments can be used in any combination of directories, file names or node ids.
- recurse into directories, unless they match norecursedirs
- test_*.py or *_test.py files, imported by their test package name.
- Test prefixed test classes (without an __init__ method)
- test_prefixed test functions or methods are test items

For examples of how to customize your test discovery Changing standard (Python) test discovery.

Within Python modules, pytest also discovers tests using the standard *unittest.TestCase* subclassing technique.

24.2 Choosing a test layout / import rules

pytest supports two common test layouts:

• putting tests into an extra directory outside your actual application code, useful if you have many functional tests or for other reasons want to keep tests separate from actual application code (often a good idea):

```
setup.py # your setuptools Python package metadata
mypkg/
    __init__.py
    appmodule.py
tests/
    test_app.py
...
```

• inlining test directories into your application package, useful if you have direct relation between (unit-)test and application modules and want to distribute your tests along with your application:

```
setup.py # your setuptools Python package metadata
mypkg/
   __init__.py
   appmodule.py
   ...
   test/
```

```
test_app.py
...
```

Important notes relating to both schemes:

• make sure that "mypkg" is importable, for example by typing once:

```
pip install -e . # install package using setup.py in editable mode
```

- avoid "__init__.py" files in your test directories. This way your tests can run easily against an installed version of mypkq, independently from the installed package if it contains the tests or not.
- With inlined tests you might put __init__.py into test directories and make them installable as part of your application. Using the pytest --pyargs mypkg invocation pytest will discover where mypkg is installed and collect tests from there. With the "external" test you can still distribute tests but they will not be installed or become importable.

Typically you can run tests by pointing to test directories or modules:

```
pytest tests/test_app.py  # for external test dirs
pytest mypkg/test/test_app.py  # for inlined test dirs
pytest mypkg  # run tests in all below test directories
pytest  # run all tests below current dir
...
```

Because of the above editable install mode you can change your source code (both tests and the app) and rerun tests at will. Once you are done with your work, you can *use tox* to make sure that the package is really correct and tests pass in all required configurations.

Note: You can use Python3 namespace packages (PEP420) for your application but pytest will still perform *test package name* discovery based on the presence of __init__.py files. If you use one of the two recommended file system layouts above but leave away the __init__.py files from your directories it should just work on Python3.3 and above. From "inlined tests", however, you will need to use absolute imports for getting at your application code.

Note: If pytest finds a "a/b/test_module.py" test file while recursing into the filesystem it determines the import name as follows:

- determine basedir: this is the first "upward" (towards the root) directory not containing an __init__.py. If e.g. both a and b contain an __init__.py file then the parent directory of a will become the basedir.
- perform sys.path.insert(0, basedir) to make the test module importable under the fully qualified import name.
- import a.b.test_module where the path is determined by converting path separators / into "." characters. This means you must follow the convention of having directory and file names map directly to the import names

The reason for this somewhat evolved importing technique is that in larger projects multiple test modules might import from each other and thus deriving a canonical import name helps to avoid surprises such as a test modules getting imported twice.

24.3 Tox

For development, we recommend to use virtualenv environments and pip for installing your application and any dependencies as well as the pytest package itself. This ensures your code and dependencies are isolated from the

system Python installation.

If you frequently release code and want to make sure that your actual package passes all tests you may want to look into tox, the virtualenv test automation tool and its pytest support. Tox helps you to setup virtualenv environments with pre-defined dependencies and then executing a pre-configured test command with options. It will run tests against the installed package and not against your source code checkout, helping to detect packaging glitches.

Continuous integration services such as Jenkins can make use of the --junitxml=PATH option to create a JUnitXML file and generate reports (e.g. by publishing the results in a nice format with the Jenkins xUnit Plugin).

24.4 Integrating with setuptools / python setup.py test / pytest-runner

You can integrate test runs into your setuptools based project with the pytest-runner plugin.

Add this to setup.py file:

```
from setuptools import setup

setup(
    #...,
    setup_requires=['pytest-runner', ...],
    tests_require=['pytest', ...],
    #...,
)
```

And create an alias into setup.cfg file:

```
[aliases]
test=pytest
```

If you now type:

```
python setup.py test
```

this will execute your tests using pytest-runner. As this is a standalone version of pytest no prior installation whatsoever is required for calling the test command. You can also pass additional arguments to pytest such as your test directory or other options using --addopts.

You can also specify other pytest-ini options in your setup.cfg file by putting them into a [tool:pytest] section:

```
[tool:pytest]
addopts = --verbose
python_files = testing/*/*.py
```

Note: Prior to 3.0, the supported section name was [pytest]. Due to how this may collide with some distutils commands, the recommended section name for setup.cfg files is now [tool:pytest].

Note that for pytest.ini and tox.ini files the section name is [pytest].

24.4.1 Manual Integration

If for some reason you don't want/can't use pytest-runner, you can write your own setuptools Test command for invoking pytest.

```
import sys
from setuptools.command.test import test as TestCommand
class PyTest (TestCommand):
   user_options = [('pytest-args=', 'a', "Arguments to pass to pytest")]
   def initialize_options(self):
       TestCommand.initialize_options(self)
       self.pytest_args = []
   def run_tests(self):
        #import here, cause outside the eggs aren't loaded
        import pytest
       errno = pytest.main(self.pytest_args)
       sys.exit(errno)
setup(
   #...,
   tests_require=['pytest'],
   cmdclass = {'test': PyTest},
```

Now if you run:

```
python setup.py test
```

this will download pytest if needed and then run your tests as you would expect it to. You can pass a single string of arguments using the --pytest-args or -a command-line option. For example:

```
python setup.py test -a "--durations=5"
```

is equivalent to running pytest --durations=5.

Basic test configuration

25.1 Command line options and configuration file settings

You can get help on command line options and values in INI-style configurations files by using the general help option:

```
pytest -h # prints options _and_ config file settings
```

This will display command line and configuration file settings which were registered by installed plugins.

25.2 initialization: determining rootdir and inifile

New in version 2.7.

pytest determines a "rootdir" for each test run which depends on the command line arguments (specified test files, paths) and on the existence of inifiles. The determined rootdir and ini-file are printed as part of the pytest header. The rootdir is used for constructing "nodeids" during collection and may also be used by plugins to store project/testrunspecific information.

Here is the algorithm which finds the rootdir from args:

- determine the common ancestor directory for the specified args that are recognised as paths that exist in the file system. If no such paths are found, the common ancestor directory is set to the current working directory.
- look for pytest.ini, tox.ini and setup.cfg files in the ancestor directory and upwards. If one is matched, it becomes the ini-file and its directory becomes the rootdir.
- if no ini-file was found, look for setup.py upwards from the common ancestor directory to determine the rootdir.
- if no setup.py was found, look for pytest.ini, tox.ini and setup.cfg in each of the specified args and upwards. If one is matched, it becomes the ini-file and its directory becomes the rootdir.
- if no ini-file was found, use the already determined common ancestor as root directory. This allows to work with pytest in structures that are not part of a package and don't have any particular ini-file configuration.

If no args are given, pytest collects test below the current working directory and also starts determining the rootdir from there.

warning custom pytest plugin commandline arguments may include a path, as in pytest --log-output ../../test.log args. Then args is mandatory, otherwise pytest uses the folder of test.log for rootdir determination (see also issue 1435). A dot . for referencing to the current working directory is also possible.

Note that an existing pytest.ini file will always be considered a match, whereas tox.ini and setup.cfg will only match if they contain a [pytest] or [tool:pytest] section, respectively. Options from multiple ini-files candidates are never merged - the first one wins (pytest.ini always wins, even if it does not contain a [pytest] section).

The config object will subsequently carry these attributes:

- config.rootdir: the determined root directory, guaranteed to exist.
- config.inifile: the determined ini-file, may be None.

The rootdir is used a reference directory for constructing test addresses ("nodeids") and can be used also by plugins for storing per-testrun information.

Example:

```
pytest path/to/testdir path/other/
```

will determine the common ancestor as path and then check for ini-files as follows:

```
# first look for pytest.ini files
path/pytest.ini
path/setup.cfg # must also contain [tool:pytest] section to match
path/tox.ini # must also contain [pytest] section to match
pytest.ini
... # all the way down to the root

# now look for setup.py
path/setup.py
setup.py
... # all the way down to the root
```

25.3 How to change command line options defaults

It can be tedious to type the same series of command line options every time you use pytest. For example, if you always want to see detailed info on skipped and xfailed tests, as well as have terser "dot" progress output, you can write it into a configuration file:

```
# content of pytest.ini
# (or tox.ini or setup.cfg)
[pytest]
addopts = -rsxX -q
```

Alternatively, you can set a PYTEST_ADDOPTS environment variable to add command line options while the environment is in use:

```
export PYTEST_ADDOPTS="-rsxX -q"
```

From now on, running pytest will add the specified options.

25.4 Builtin configuration file options

minversion

Specifies a minimal pytest version required for running tests. minversion = 2.1 # will fail if we run with pytest-2.0

addopts

Add the specified OPTS to the set of command line arguments as if they had been specified by the user. Example: if you have this ini file content:

```
[pytest]
addopts = --maxfail=2 -rf # exit after 2 failures, report fail info
```

issuing pytest test_hello.py actually means:

```
pytest --maxfail=2 -rf test_hello.py
```

Default is to add no options.

norecursedirs

Set the directory basename patterns to avoid when recursing for test discovery. The individual (fnmatch-style) patterns are applied to the basename of a directory to decide if to recurse into it. Pattern matching characters:

```
* matches everything
? matches any single character
[seq] matches any character in seq
[!seq] matches any char not in seq
```

Default patterns are '.*', 'build', 'dist', 'CVS', '_darcs', '{arch}', '*.egg'. Setting a norecursedirs replaces the default. Here is an example of how to avoid certain directories:

```
# content of pytest.ini
[pytest]
norecursedirs = .svn _build tmp*
```

This would tell pytest to not look into typical subversion or sphinx-build directories or into any tmp prefixed directory.

testpaths

New in version 2.8.

Sets list of directories that should be searched for tests when no specific directories, files or test ids are given in the command line when executing pytest from the *rootdir* directory. Useful when all project tests are in a known location to speed up test collection and to avoid picking up undesired tests by accident.

```
# content of pytest.ini
[pytest]
testpaths = testing doc
```

This tells pytest to only look for tests in testing and doc directories when executing from the root directory.

python_files

One or more Glob-style file patterns determining which python files are considered as test modules.

python_classes

One or more name prefixes or glob-style patterns determining which classes are considered for test collection. Here is an example of how to collect tests from classes that end in Suite:

```
# content of pytest.ini
[pytest]
python_classes = *Suite
```

Note that unittest. TestCase derived classes are always collected regardless of this option, as unittest's own collection framework is used to collect those tests.

python_functions

One or more name prefixes or glob-patterns determining which test functions and methods are considered tests. Here is an example of how to collect test functions and methods that end in _test:

```
# content of pytest.ini
[pytest]
python_functions = *_test
```

Note that this has no effect on methods that live on a unittest . TestCase derived class, as unittest's own collection framework is used to collect those tests.

See Changing naming conventions for more detailed examples.

doctest_optionflags

One or more doctest flag names from the standard doctest module. See how pytest handles doctests.

confcutdir

Sets a directory where search upwards for <code>conftest.py</code> files stops. By default, pytest will stop searching for <code>conftest.py</code> files upwards from <code>pytest.ini/tox.ini/setup.cfg</code> of the project if any, or up to the file-system root.

Setting up bash completion

When using bash as your shell, pytest can use argcomplete (https://argcomplete.readthedocs.io/) for auto-completion. For this argcomplete needs to be installed **and** enabled.

Install argcomplete using:

sudo pip install 'argcomplete>=0.5.7'

For global activation of all argcomplete enabled python applications run:

sudo activate-global-python-argcomplete

For permanent (but not global) pytest activation, use:

register-python-argcomplete pytest >> ~/.bashrc

For one-time activation of argcomplete for pytest only, use:

eval "\$(register-python-argcomplete pytest)"

Backwards Compatibility Policy

Keeping backwards compatibility has a very high priority in the pytest project. Although we have deprecated functionality over the years, most of it is still supported. All deprecations in pytest were done because simpler or more efficient ways of accomplishing the same tasks have emerged, making the old way of doing things unnecessary.

With the pytest 3.0 release we introduced a clear communication scheme for when we will actually remove the old busted joint and politely ask you to use the new hotness instead, while giving you enough time to adjust your tests or raise concerns if there are valid reasons to keep deprecated functionality around.

To communicate changes we are already issuing deprecation warnings, but they are not displayed by default. In pytest 3.0 we changed the default setting so that pytest deprecation warnings are displayed if not explicitly silenced (with --disable-pytest-warnings).

We will only remove deprecated functionality in major releases (e.g. if we deprecate something in 3.0 we will remove it in 4.0), and keep it around for at least two minor releases (e.g. if we deprecate something in 3.9 and 4.0 is the next release, we will not remove it in 4.0 but in 5.0).

Contribution getting started

Contributions are highly welcomed and appreciated. Every little help counts, so do not hesitate!

Contribution links

- Contribution getting started
 - Feature requests and feedback
 - Report bugs
 - Fix bugs
 - Implement features
 - Write documentation
 - Submitting Plugins to pytest-dev
 - Preparing Pull Requests on GitHub

29.1 Feature requests and feedback

Do you like pytest? Share some love on Twitter or in your blog posts!

We'd also like to hear about your propositions and suggestions. Feel free to submit them as issues and:

- Explain in detail how they should work.
- Keep the scope as narrow as possible. This will make it easier to implement.

29.2 Report bugs

Report bugs for pytest in the issue tracker.

If you are reporting a bug, please include:

- Your operating system name and version.
- Any details about your local setup that might be helpful in troubleshooting, specifically Python interpreter version, installed libraries and pytest version.
- Detailed steps to reproduce the bug.

If you can write a demonstration test that currently fails but should pass (xfail), that is a very useful commit to make as well, even if you can't find how to fix the bug yet.

29.3 Fix bugs

Look through the GitHub issues for bugs. Here is a filter you can use: https://github.com/pytest-dev/pytest/labels/bug *Talk* to developers to find out how you can fix specific bugs.

Don't forget to check the issue trackers of your favourite plugins, too!

29.4 Implement features

Look through the GitHub issues for enhancements. Here is a filter you can use: https://github.com/pytest-dev/pytest/labels/enhancement

Talk to developers to find out how you can implement specific features.

29.5 Write documentation

Pytest could always use more documentation. What exactly is needed?

- More complementary documentation. Have you perhaps found something unclear?
- Documentation translations. We currently have only English.
- Docstrings. There can never be too many of them.
- Blog posts, articles and such they're all very appreciated.

You can also edit documentation files directly in the GitHub web interface, without using a local copy. This can be convenient for small fixes.

29.6 Submitting Plugins to pytest-dev

Pytest development of the core, some plugins and support code happens in repositories living under the pytest-dev organisations:

- pytest-dev on GitHub
- pytest-dev on Bitbucket

All pytest-dev Contributors team members have write access to all contained repositories. Pytest core and plugins are generally developed using *pull requests* to respective repositories.

The objectives of the pytest-dev organisation are:

- Having a central location for popular pytest plugins
- Sharing some of the maintenance responsibility (in case a maintainer no longer wishes to maintain a plugin)

You can submit your plugin by subscribing to the pytest-dev mail list and writing a mail pointing to your existing pytest plugin repository which must have the following:

- PyPI presence with a setup.py that contains a license, pytest- prefixed name, version number, authors, short and long description.
- a tox.ini for running tests using tox.
- a README.txt describing how to use the plugin and on which platforms it runs.

- a LICENSE.txt file or equivalent containing the licensing information, with matching info in setup.py.
- an issue tracker for bug reports and enhancement requests.
- a changelog

If no contributor strongly objects and two agree, the repository can then be transferred to the pytest-dev organisation.

Here's a rundown of how a repository transfer usually proceeds (using a repository named joedoe/pytest-xyz as example):

- joedoe transfers repository ownership to pytest-dev administrator calvin.
- calvin creates pytest-xyz-admin and pytest-xyz-developers teams, inviting joedoe to both as maintainer.
- calvin transfers repository to pytest-dev and configures team access:
 - pytest-xyz-admin admin access;
 - pytest-xyz-developers write access;

The pytest-dev/Contributors team has write access to all projects, and every project administrator is in it. We recommend that each plugin has at least three people who have the right to release to PyPI.

Repository owners can rest assured that no pytest-dev administrator will ever make releases of your repository or take ownership in any way, except in rare cases where someone becomes unresponsive after months of contact attempts. As stated, the objective is to share maintenance and avoid "plugin-abandon".

29.7 Preparing Pull Requests on GitHub

Note: What is a "pull request"? It informs project's core developers about the changes you want to review and merge. Pull requests are stored on GitHub servers. Once you send a pull request, we can discuss its potential modifications and even add more commits to it later on.

There's an excellent tutorial on how Pull Requests work in the GitHub Help Center, but here is a simple overview:

- 1. Fork the pytest GitHub repository. It's fine to use pytest as your fork repository name because it will live under your user.
- 2. Clone your fork locally using git and create a branch:

```
$ git clone git@github.com:YOUR_GITHUB_USERNAME/pytest.git
$ cd pytest
# now, to fix a bug create your own branch off "master":

$ git checkout -b your-bugfix-branch-name master
# or to instead add a feature create your own branch off "features":

$ git checkout -b your-feature-branch-name features
```

Given we have "major.minor.micro" version numbers, bugfixes will usually be released in micro releases whereas features will be released in minor releases and incompatible changes in major releases.

If you need some help with Git, follow this quick start guide: https://git.wiki.kernel.org/index.php/QuickStart

3. Install tox

Tox is used to run all the tests and will automatically setup virtualenvs to run the tests in. (will implicitly use http://www.virtualenv.org/en/latest/):

```
$ pip install tox
```

4. Run all the tests

You need to have Python 2.7 and 3.5 available in your system. Now running tests is as simple as issuing this command:

```
$ python3 runtox.py -e linting,py27,py35
```

This command will run tests via the "tox" tool against Python 2.7 and 3.5 and also perform "lint" coding-style checks. runtox.py is a thin wrapper around tox which installs from a development package index where newer (not yet released to PyPI) versions of dependencies (especially py) might be present.

5. You can now edit your local working copy.

You can now make the changes you want and run the tests again as necessary.

To run tests on Python 2.7 and pass options to pytest (e.g. enter pdb on failure) to pytest you can do:

```
$ python3 runtox.py -e py27 -- --pdb
```

Or to only run tests in a particular test module on Python 3.5:

```
$ python3 runtox.py -e py35 -- testing/test_config.py
```

6. Commit and push once your tests pass and you are happy with your change(s):

```
$ git commit -a -m "<commit message>"
$ git push -u
```

Make sure you add a message to CHANGELOG.rst and add yourself to AUTHORS. If you are unsure about either of these steps, submit your pull request and we'll help you fix it up.

7. Finally, submit a pull request through the GitHub website using this data:

```
head-fork: YOUR_GITHUB_USERNAME/pytest
compare: your-branch-name

base-fork: pytest-dev/pytest
base: master  # if it's a bugfix
base: features  # if it's a feature
```

Talks and Tutorials

Next Open Trainings

professional testing with pytest and tox, 27-29th June 2016, Freiburg, Germany

30.1 Talks and blog postings

- pytest Rapid Simple Testing, Florian Bruhin, Swiss Python Summit 2016.
- Improve your testing with Pytest and Mock, Gabe Hollombe, PyCon SG 2015.
- Introduction to pytest, Andreas Pelme, EuroPython 2014.
- Advanced Uses of py.test Fixtures, Floris Bruynooghe, EuroPython 2014.
- Why i use py.test and maybe you should too, Andy Todd, Pycon AU 2013
- 3-part blog series about pytest from @pydanny alias Daniel Greenfeld (January 2014)
- pytest: helps you write better Django apps, Andreas Pelme, DjangoCon Europe 2014.
- pytest fixtures: explicit, modular, scalable
- Testing Django Applications with pytest, Andreas Pelme, EuroPython 2013.
- Testes pythonics com py.test, Vinicius Belchior Assef Neto, Plone Conf 2013, Brazil.
- Introduction to py.test fixtures, FOSDEM 2013, Floris Bruynooghe.
- pytest feature and release highlights, Holger Krekel (GERMAN, October 2013)
- pytest introduction from Brian Okken (January 2013)
- pycon australia 2012 pytest talk from Brianna Laugher (video, slides, code)
- pycon 2012 US talk video from Holger Krekel
- monkey patching done right (blog post, consult monkeypatch plugin for up-to-date API)

Test parametrization:

- generating parametrized tests with fixtures.
- test generators and cached setup
- parametrizing tests, generalized (blog post)

• putting test-hooks into local or global plugins (blog post)

Assertion introspection:

• (07/2011) Behind the scenes of pytest's new assertion rewriting

Distributed testing:

• simultaneously test your code on all platforms (blog entry)

Plugin specific examples:

- skipping slow tests by default in pytest (blog entry)
- many examples in the docs for plugins

Alex Gaynor

@alex gaynor

py.test is pretty much the best thing ever. Not entirely sure why you'd use anything else.

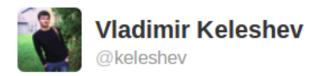

theuni @theuni

Switched test runner for #batou to #pytest picked up everything correctly, no failing tests. Correct skips. Kudos to @hpk42 Very impressed.

David Cramer @zeeg

Converting all my projects to py.test. Not sure why it took me so long. /cc @hpk42

Seriously, #pytest is among my top-5 reasons to use #python.

Project examples

Here are some examples of projects using pytest (please send notes via Contact channels):

- PyPy, Python with a JIT compiler, running over 21000 tests
- the MoinMoin Wiki Engine
- · sentry, realtime app-maintenance and exception tracking
- Astropy and affiliated packages
- tox, virtualenv/Hudson integration tool
- PIDA framework for integrated development
- PyPM ActiveState's package manager
- Fom a fluid object mapper for FluidDB
- applib cross-platform utilities
- six Python 2 and 3 compatibility utilities
- pediapress MediaWiki articles
- mwlib mediawiki parser and utility library
- The Translate Toolkit for localization and conversion
- execnet rapid multi-Python deployment
- pylib cross-platform path, IO, dynamic code library
- Pacha configuration management in five minutes
- bbfreeze create standalone executables from Python scripts
- pdb++ a fancier version of PDB
- py-s3fuse Amazon S3 FUSE based filesystem
- waskr WSGI Stats Middleware
- guachi global persistent configs for Python modules
- Circuits lightweight Event Driven Framework
- pygtk-helpers easy interaction with PyGTK
- QuantumCore statusmessage and repoze openid plugin
- pydataportability libraries for managing the open web

- XIST extensible HTML/XML generator
- tiddlyweb optionally headless, extensible RESTful datastore
- fancycompleter for colorful tab-completion
- · Paludis tools for Gentoo Paludis package manager
- Gerald schema comparison tool
- · abjad Python API for Formalized Score control
- bu a microscopic build system
- katcp Telescope communication protocol over Twisted
- · kss plugin timer
- pyudev a pure Python binding to the Linux library libudev
- pytest-localserver a plugin for pytest that provides a httpserver and smtpserver
- pytest-monkeyplus a plugin that extends monkeypatch

These projects help integrate pytest into other Python frameworks:

- pytest-django for Django
- · zope.pytest for Zope and Grok
- pytest_gae for Google App Engine
- There is some work underway for Kotti, a CMS built in Pyramid/Pylons

31.1 Some organisations using pytest

- Square Kilometre Array, Cape Town
- Some Mozilla QA people use pytest to distribute their Selenium tests
- Tandberg
- Shootq
- Stups department of Heinrich Heine University Duesseldorf
- cellzome
- · Open End, Gothenborg
- Laboratory of Bioinformatics, Warsaw
- · merlinux, Germany
- · ESSS, Brazil
- many more ... (please be so kind to send a note via *Contact channels*)

Some Issues and Questions

Note: This FAQ is here only mostly for historic reasons. Checkout pytest Q&A at Stackoverflow for many questions and answers related to pytest and/or use *Contact channels* to get help.

32.1 On naming, nosetests, licensing and magic

32.1.1 How does pytest relate to nose and unittest?

pytest and nose share basic philosophy when it comes to running and writing Python tests. In fact, you can run many tests written for nose with pytest. nose was originally created as a clone of pytest when pytest was in the 0.8 release cycle. Note that starting with pytest-2.0 support for running unittest test suites is majorly improved.

32.1.2 how does pytest relate to twisted's trial?

Since some time pytest has builtin support for supporting tests written using trial. It does not itself start a reactor, however, and does not handle Deferreds returned from a test in pytest style. If you are using trial's unittest. Test Case chances are that you can just run your tests even if you return Deferreds. In addition, there also is a dedicated pytest-twisted plugin which allows you to return deferreds from pytest-style tests, allowing the use of *pytest fixtures: explicit, modular, scalable* and other features.

32.1.3 how does pytest work with Django?

In 2012, some work is going into the pytest-django plugin. It substitutes the usage of Django's manage.py test and allows the use of all pytest features most of which are not available from Django directly.

32.1.4 What's this "magic" with pytest? (historic notes)

Around 2007 (version 0.8) some people thought that pytest was using too much "magic". It had been part of the pylib which contains a lot of unrelated python library code. Around 2010 there was a major cleanup refactoring, which removed unused or deprecated code and resulted in the new pytest PyPI package which strictly contains only test-related code. This release also brought a complete pluginification such that the core is around 300 lines of code and everything else is implemented in plugins. Thus pytest today is a small, universally runnable and customizable testing framework for Python. Note, however, that pytest uses metaprogramming techniques and reading its source is thus likely not something for Python beginners.

A second "magic" issue was the assert statement debugging feature. Nowadays, pytest explicitly rewrites assert statements in test modules in order to provide more useful *assert feedback*. This completely avoids previous issues of confusing assertion-reporting. It also means, that you can use Python's -0 optimization without losing assertions in test modules.

pytest contains a second, mostly obsolete, assert debugging technique invoked via --assert=reinterpret: When an assert statement fails, pytest re-interprets the expression part to show intermediate values. This technique suffers from a caveat that the rewriting does not: If your expression has side effects (better to avoid them anyway!) the intermediate values may not be the same, confusing the reinterpreter and obfuscating the initial error (this is also explained at the command line if it happens).

You can also turn off all assertion interaction using the --assert=plain option.

32.1.5 Why can I use both pytest and py.test commands?

pytest used to be part of the py package, which provided several developer utilities, all starting with py.<TAB>, thus providing nice TAB-completion. If you install pip install pycmd you get these tools from a separate package. Once pytest became a separate package, the py.test name was retained due to avoid a naming conflict with another tool. This conflict was eventually resolved, and the pytest command was therefore introduced. In future versions of pytest, we may deprecate and later remove the py.test command to avoid perpetuating the confusion.

32.2 pytest fixtures, parametrized tests

32.2.1 Is using pytest fixtures versus xUnit setup a style question?

For simple applications and for people experienced with nose or unittest-style test setup using xUnit style setup probably feels natural. For larger test suites, parametrized testing or setup of complex test resources using fixtures may feel more natural. Moreover, fixtures are ideal for writing advanced test support code (like e.g. the monkeypatch, the tmpdir or capture fixtures) because the support code can register setup/teardown functions in a managed class/module/function scope.

32.2.2 Can I yield multiple values from a fixture function?

There are two conceptual reasons why yielding from a factory function is not possible:

- If multiple factories yielded values there would be no natural place to determine the combination policy in real-world examples some combinations often should not run.
- Calling factories for obtaining test function arguments is part of setting up and running a test. At that point it is not possible to add new test calls to the test collection anymore.

However, with pytest-2.3 you can use the *Fixtures as Function arguments* decorator and specify params so that all tests depending on the factory-created resource will run multiple times with different parameters.

You can also use the pytest_generate_tests hook to implement the parametrization scheme of your choice. See also *Parametrizing tests* for more examples.

32.3 pytest interaction with other packages

32.3.1 Issues with pytest, multiprocess and setuptools?

On Windows the multiprocess package will instantiate sub processes by pickling and thus implicitly re-import a lot of local modules. Unfortunately, setuptools-0.6.11 does not if __name__=='__main__' protect its generated command line script. This leads to infinite recursion when running a test that instantiates Processes.

As of mid-2013, there shouldn't be a problem anymore when you use the standard setuptools (note that distribute has been merged back into setuptools which is now shipped directly with virtualenv).

Contact channels

- pytest issue tracker to report bugs or suggest features (for version 2.0 and above).
- pytest on stackoverflow.com to post questions with the tag pytest. New Questions will usually be seen by pytest users or developers and answered quickly.
- Testing In Python: a mailing list for Python testing tools and discussion.
- pytest-dev at python.org (mailing list) pytest specific announcements and discussions.
- pytest-commit at python.org (mailing list): for commits and new issues
- contribution guide for help on submitting pull requests to bitbucket (including using git via gitifyhg).
- #pylib on irc.freenode.net IRC channel for random questions.
- private mail to Holger.Krekel at gmail com if you want to communicate sensitive issues
- merlinux.eu offers pytest and tox-related professional teaching and consulting.
